Various types of air domination systems are being considered by the Air Force to enable a military force to dominate an area from the air for extended periods and deny enemy movements and maneuvering. Current systems under consideration are standard weaponized UAS or small expendable loitering weapons, fitted with imaging sensors, such as the Low-Cost Autonomous Attack System (LOCAAS). Operating in swarms of "intelligent munitions" weapons, the LOCAAS can autonomously search for and destroy critical mobile targets while aiming over a wide combat area. Recent enhancements of the LOCAAS concept introduced man-in-the-loop functionality to enable retargeting and the ability to abort attack by a human controller when required. Further enhancements could integrate the LOCAAS into a "Surveilling Miniature Attack Cruise Missile" (SMACM) "mothership" carrying four LOCAAS units. The mothership will be able to support the units with targeting, surveillance, and communication support and extend the range and persistence of the basic version beyond 250 nautical miles. LOCAAS and SMACM are designed to operate in open area and pursue stationary and mobile targets of opportunities as soon as they are exposed in the open.

3955 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

A tremendous amount of work has yet to be done in the area of autonomous systems as a weapon. Current systems have less than optimal loiter times and are not readily adaptable to the shipboard environment and the strike fighter mission. As well, advances in interoperability, materials technology, and fusing have not been incorporated across the unmanned systems spectrum.

Figure 30 summarizes the goals for weaponry for unmanned systems.

Figure 30. Weaponry Goals for Unmanned Systems

3956 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

5 Operating Environment

5.1 Introduction

The world's markets, technologies, and regulatory environments for unmanned systems are evolving rapidly and creating opportunities in platforms, payloads, leasing, operations, and maintenance. DoD is looking beyond Iraq and Afghanistan towards a world of rapid deployments to trouble spots where airfields may not be available. After U.S. forces begin withdrawal from Afghanistan in 2014 in accordance with presidential planning, commanders expect to focus on contingency missions where the United States may have no established presence. UAS must then operate from ships or beaches rather than from fixed bases. Airborne launch of unmanned platforms is another approach.

Unmanned systems are better suited than manned platforms in some circumstances. In anticipation of such use, every segment of unmanned systems — the deployed platform, control station(s), and control link(s) — must all be considered from the earliest stages of program development. The environment must encompass all influences on this extended system, not just focus on the platform itself. System technology program requirements must be outlined in a CONOPS that details how the system is to be used in the intended physical operating environment and provides a baseline for all system requirements.

In addition to operating unmanned systems in strenuous physical environments, programs must also account for the ability to operate within existing regulations and within socially acceptable means. There will always be regulatory uncertainty when a revolutionary technology is introduced, as is the case with unmanned systems. A prime example is the consideration of UAS flights in the NAS, where UAS must operate within the FAA Federal Aviation Regulations (FARs). Even in cases where UAS do meet all applicable FARs, users of the UAS must consider the safety of the general public and abide by applicable privacy laws. Similarly, UGS intending to operate on U.S. public roads must at a minimum comply with Department of Transportation (DoT) regulations and federal, state, and local motor vehicle laws, but should additionally show safety and traffic efficiency enhancements to gain acceptance from the general public.

The unmanned systems safety guide for DoD acquisition references DoDI 5000.1, which instructs program managers to prevent environment, safety, and occupational health (ESOH) hazards, where possible, and manage ESOH hazards where they cannot be avoided. The unmanned systems must also comply to the Army equipment spectrum certification (ESC), which allows program management offices and others to apply for new equipment frequency allocations (i.e., spectrum certifications), request changes to existing spectrum certifications, request host nation coordination, and submit questions. The system tracks these "requests" and provides real-time status updates and mechanisms to collaborate with the Spectrum Management Office, which processes the request. Currently, the ESC process manager supports only Army requests while Navy and Air Force versions of this system are under development. Also, unmanned systems must meet information assurance requirements for their complex software systems as these systems must interact with other systems and humans through networked C2 systems to share information and control these systems. The Navy and Air Force have differing versions of this same process.

3957 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

5.2 Problem Statement

The operating environment of the unmanned system is a critical factor in determining the appropriate level of autonomy and the capability to maneuver as needed to accomplish the mission.

The intended physical operating environment provided in a CONOPS and other program requirement documents will help determine the level of technology that must be applied to the unmanned system. More stressing physical environments will most notably affect the level of autonomy required, along with the capability to act on the situation at hand.

Similarly, in the regulatory environment, program plans must account for the regulatory hurdles that are typical with revolutionary technologies. Individual technologies must be carefully examined at every level in the system until the appropriate levels of technological advances are defined to be capable of overcoming such hurdles.

These concerns are especially important and apply to A2/AD scenario planning factors. These factors include technologies supporting survivability, anti-jam, all weather, and persistence capabilities as described in Chapter 4.

5.3 Physical Environment

The physical operating environment provides the basis for the unmanned systems capabilities. Ideally, unmanned systems should be able to adapt to any environment but, to constrain the problem, many state-of-the-art unmanned systems are currently designed from the ground up to operate within an assumed environment.

The UAS physical operating environment may vary greatly. Generally, UAS will operate in similar conditions as manned aircraft, i.e., in all weather, from low to high altitude, and in airspace that is congested and possibly contested. Some UAS, such as Triton, are intended to fly in maritime environments at both very high and low altitudes. Flights at lower altitudes must consider saltwater and humidity in both design and operation, while high-altitude operations must consider extreme temperatures and the lack of air pressure. Also, the altitude transitions through weather and additional stresses will require additional capability considerations.

The physical operating environment determines the basis for UGS capabilities. Operations for future UGS will vary from occurring in structured and semi-structured environments to occurring outside a defined perimeter on semi-structured to unstructured terrain in support of force protection or physical security missions in more hostile environments. UGS maneuvering must account for environmental conditions (e.g., obstacles, threats, road conditions) in addition to the system performance. Further environmental classifications, such as urban/rural, forest/open, road/non-road, indoor/outdoor, must be addressed with regard to UGS.

DARPA and the auto industry continue to pursue automated technologies that could allow UGS to operate in a variety of conditions. Current efforts allow vehicles to operate within pavement lines, operate in sequence, stop when objects are ahead, and take caution when foreign objects are near (such as deer). Many of these efforts are intended to enhance vehicular safety, but also assist unmanned systems technology through increasing automation.

3958 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The intended physical operating environments for UMS are in and around harbors, strategically placed within major shipping routes such as the Strait of Hormuz, or possibly out in the open ocean. Although maneuvering with no roads and no "water traffic controller," USVs must be capable of avoiding ships, docks, floating debris, and navigation aids and must stay within proper navigable waters (i.e., not run aground). In addition, USVs must operate in accordance with collision regulations (COLREGS).[68] Because not all maritime traffic (including military and commercial) always follows the COLREGS, however, autonomous behavior is more difficult to develop for USVs.

On the other hand, although UUVs have the risk of running into underwater obstructions, they do not typically have to worry about other vehicles. Furthermore, there are also no navigation rules for underwater operation. For UUVs operating in a stressing environment such as open ocean, the technology must be capable of providing enough power to last long durations of time while autonomously performing their missions even when communication links are limited.

5.4 Policy and Regulatory Environment

Unmanned systems programs must consider all the policies and regulations of the appropriate authorities as program planning begins. UGS may need to operate on public roads where DoT is the regulatory authority within the United States, while UGS on foreign lands must remain within the policies of the host nations. Projects conducted by the National Highway Traffic Safety Administration will provide valuable data to develop safety standards and performance requirements, which will help ensure the safe testing and subsequent operation of autonomous vehicles on public roads. New technologies for UGS must be tested for safety and verified by the appropriate regulatory authority.

The primary regulations controlling the safe navigation of U.S. vessels are the navigation rules published by the U.S. Coast Guard.[69] These rules are applicable to international and inland waters. The international waters rules are based on the 1972 International Regulations for Prevention of Collision at Sea (72 COLREGS), as amended, a treaty that the United States adopted in 1977.

The Navigation Safety Advisory Council (NAVSAC) was established by the U.S. Congress to advise the Secretary of Transportation, via the Commandant, U.S. Coast Guard, on matters relating to the prevention of collisions, rammings, and groundings. In May 2011, NAVSAC recommended to the Coast Guard that UMS be required to comply with the navigation rules, including some amendments deemed necessary for UMS compliance.

In addition to safe navigation rules, UMS must comply with other rules and regulations, such as for RF communication equipment operation and for environmental restrictions covering the operation of sonars and underwater acoustic instruments.

Safe operation of aircraft within domestic national airspace is governed by the FARs maintained and published by the FAA. Compliance with the FARs requires a pilot in the cockpit of the aircraft to "see and avoid" other aviation traffic. Therefore, UAS by nature cannot comply

[68] International Regulations for Prevention of Collision at Sea (COLREGS), 1972.
[69] COMDTINST M16672.2D, Navigation Rules, International – Inland, 23 November 2011.

3959 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

with the FARs. DoD UAS operations outside of restricted or warning areas within the NAS are currently required to obtain a Certificate of Waiver or Authorization (COA) from the FAA in accordance with FAA Order 7610.4, Chapter 12, Section 9.[70] The order identifies information that should be included in the COA request, including a description of the intended flight operations, UAS characteristics, and lost link procedures.

Outside U.S. sovereign national airspace, foreign nations have designated civil aviation authorities (similar to the FAA) that regulate and exercise governance over their sovereign national airspace. Furthermore, when operating in international airspace (i.e., over the high seas) DoD UAS observe International Civil Aviation Organization (ICAO) flight procedures when practical and compatible with their mission. However, in accordance with DoD policy (and consistent with international law) when operational situations do not lend themselves to ICAO flight procedures, such operations may be conducted under due regard.[71] In designated combat airspace, DoD UAS operate in accordance with instructions provided by the designated airspace control authority.[72]

5.4.1 Testing and Certification

Testing of UMS is required for the Military Departments to be able to certify compliance with regulations and demonstrate safe operations.

USVs must meet the same requirements of a manned craft or boat that is intended to be put into service. Testing unmanned systems in general is a significant challenge and can be very costly. For example, if it is impossible to put a man aboard a USV, the amount of time and expense increases significantly to verify that the propulsion system is working correctly. The Navy has developed a guide for testing USVs and drafted an approach to certifying USVs. The guide and draft certification method are available from the Naval Surface Warfare Center Carderock, Detachment Norfolk.[73]

To be able to fly in any airspace, DoD UAS are required to be certified as airworthy. Airworthiness certification is a core acquisition and engineering process conducted for system safety and takes into account material, service life, and mission requirements within the intended airspace.

Level of certification depends on the mission requirements of the system. A certification allowing unlimited NAS access may be cost prohibitive and unnecessary. For systems that do not require full airspace access or are constrained by cost or other technical hurdles, military departments may impose operational restrictions when issuing airworthiness statements for UAS. Examples include flights within a shipboard environment, only in uncongested airspace, or under other certain conditions with specific safety precautions. UAS may be allowed very limited access to the NAS, such as flights limited only within restricted or warning areas or only over unpopulated areas with other restrictions if little is known about the system or the operational risks are deemed too high to permit operations within the NAS.

3960 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

5.4.2 Sense and Avoid (SAA) Capability

SAA is a technical approach that has been proposed to bridge the gap between the FAR requirement for a pilot in the cockpit to "see and avoid" and the "unmanned" nature of UAS. In general, an SAA system should include the ability to perform the eight functions listed in Figure 31. It should be noted that for DoD UAS, expanded access to the NAS based on SAA technology will require continued use of COAs until current FAA policy, guidance, or regulations can be changed.

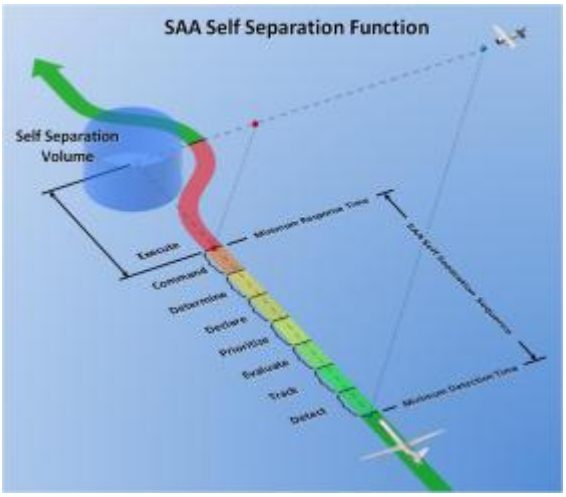

Figure 31. SAA Self-Separation Functions

5.4.3 UAS Executive Committee (ExCom)

The UAS ExCom was developed from a recommendation on conflict and dispute resolution from the 2009 National Defense Authorization Act. It is a focal point for senior leaders from DoD, FAA, the National Aeronautics and Space Administration, and the Department of Homeland Security to resolve any policy and procedural disputes and to identify solutions to enable the integration of DoD and other federal agency UAS into the NAS.

The UAS ExCom approved the UAS NAS Access Plan in October 2010, which addresses the milestones, policy recommendations, flight standards, and operating procedures necessary to provide a path for UAS integration into the NAS. The ExCom continues to work on many of the issues and recommendations identified in the plan, including continued improvements to the COA process as well as policy and procedural updates to enable significant improvement in UAS NAS access. In addition, the ExCom extended the COA expiration interval from 12 to 24 months and formalized an agreement on allowing transition from Class D airspace to adjacent Restricted or Warning areas. The ExCom is actively working to improve several other policy-related UAS issues, including

- Developing processes and procedures to allow multiple unmanned and manned operations in Class D airspace
- Simplifying the process for UAS to operate in Class D airspace from military airfields
- Simplifying the process for, and expanding the access of, SUAS to operate in Class G airspace
- Allowing UAS flights in remote operating areas with limited restrictions

5.5 Technology Application

An unmanned system may include a SoS. For example, a USV may host a UAS and UUS, or a UAS can provide inflight refueling to another UAS, or a UAS may be deployed as a communication relay station for UGS. Unmanned systems may be part of a greater system including manned elements as well. Technology developments must assess the impact each has across the rest of the system components or other systems.

3961 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Technology will improve the performance of our systems and allow them to last longer, to use fewer people, to cost less, and to provide more relevant information, where it's needed and when it's needed.

5.5.1 Unmanned Aircraft Systems

One of the key capabilities UAS currently provide to the warfighter is persistence, for example, persistent ISR. Technology improvements can expand persistence much further, but programs must consider the operating environment while incorporating the technology. As an example, one technology application is onboard data processing. This automation technology can help minimize critical bandwidth necessary to transmit ISR data to the warfighter and may also be suitable for reducing the intelligence officer workload and decreasing the time in the kill chain.

Key technology enablers that UAS will encounter in operational environments include C2 links, SAA systems, sensors and displays, separation algorithms, and interoperability.

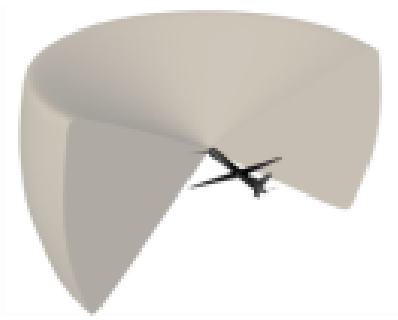
5.5.1.1 C2 Links

As an essential component of UAS by definition, solutions to problems associated with link spectrum availability, latency, and reliability must be developed in all operating environments. Spectrum considerations should be fully understood for UAS to operate at any given location for C2 and also for SAA (where radar is employed). For C2 within LOS, the United States and other countries have an approved spectrum allocation to globally use the Aeronautical Mobile (Route) Service 5030–5091 MHz band. For BLOS, the World Radiocommunications Conference (WRC) was unable to reach agreement at the WRC-12, but will continue studies for decision at WRC-15. The WRC-12 decided that no additional spectrum allocation was required for SAA purposes.

5.5.1.2 SAA Systems

An SAA system, whether ground, air, other, or integrated, will result from the effective use of many technologies. The SAA system will be a SoS, including sensors to detect and track, C2 subsystems to transmit information to a display providing situational awareness to a qualified pilot/operator, and algorithms to recommend or implement maneuvers depending on varying degrees of autonomy. Complex SAA systems may allow for formation flights or multiple shipboard operations in both SUAS and large UAS environments, all while preserving or enhancing flight safety.

5.5.1.2.1 Ground-Based SAA (GBSAA) Systems



A GBSAA system is designed to provide safe separation for UAS operations within a prescribed volume of airspace using a ground-based system of sensors, displays, communications, and software. The sensors perform detect and track functions while algorithms and/or displays assist the pilot/operator with the requirement to evaluate, prioritize, declare, and determine the best course of action to avoid a hazard. The mission-critical information is provided to the pilot/operator in a GCS or at the operating station to enable the pilot/operator to

3962 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

make decisions to safely navigate the airspace. Future developments may automate maneuvers and allow more efficient use of the airspace and the easing of air traffic management tasks.

5.5.1.2.2 Airborne Sense and Avoid (ABSAA) Systems

ABSAA development efforts are focusing on an onboard capability to perform both self-separation and collision avoidance to ensure an appropriate level of safety. The capability is intended to give pilot/operators the ability to avoid conflict and collision avoidance with other aircraft in a safe and efficient manner in all classes of airspace. Early versions of this technology may function similarly to early phases of GBSAA by requiring the pilot/operator to initiate maneuvers, but work is being done to enable autonomous action by the aircraft, or pilot-on-the-loop operations, where the system can identify and react to conflicts. Current programs have phased validation schedules for flights within airspace in which DoD is authorized to operate with due regard, en-route/Class A, and divert/Class E/Class G operations as technology innovation and integration allow.

5.5.1.3 Sensors and Displays

Although developing common and interoperable sensors across multiple types of control systems and extensible to multiple platforms is best for the current fiscal environment, UAS sensors must be customized to the mission environment. Miniaturization of sensors will allow additional capabilities on smaller UAS and/or will enable the capability to collect more information aboard a single platform. Displays built for SAA functions should be common and compatible across the Services, regardless of GBSAA or ABSAA applications, as well as across air traffic services (see Figure 32). This compatibility will reduce training costs and allow the development of common terminology and understanding.

Figure 32. UAS Pilot Simulator Training

5.5.1.4 Separation Algorithms

For the foreseeable future, a pilot/operator will have direct decision authority for all UAS actions; this approach is known as “pilot in the loop.” Predicated on the failure of self-separation and approaching collision avoidance scenarios, the addition of separation algorithms will aid the pilot/operator in completing the mission. Such algorithms will also be needed for autonomous systems. This capability applies in the NAS, foreign airspace, and combat zones, but may be most applicable in open ocean and other areas where flights would be conducted under “due regard” regulations where air traffic services are not available.

5.5.1.5 Interoperability

UAS will be operating in an increasingly crowded airspace with the potential need to interact with manned assets. The UI2 CBA identified and prioritized IOP gaps in airspace

3963 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

integration and interoperability capabilities. Decision makers on the ground must be able to access sensor systems for both manned and unmanned aircraft to enhance situational awareness. Video data must be capable of transferring between aircraft to maintain ISR continuity. Therefore, interoperability standards must be in place so the right information gets to the right people. Initial stages of this type of interoperability were demonstrated during the Army's Manned Unmanned Systems Integration Capability (MUSIC) exercise in September 2011. This technology needs continued maturation across the military departments to meet DoD interoperability goals.

5.5.1.6 Other Technologies

Technology can be used to improve survivability under hostile environments and also improve overall reliability of unmanned systems. Improved reliability will make them more acceptable to a cautious public. Power systems can allow the endurance of a UAS to expand further beyond today's limited envelope. Also, as sensor payloads continue to improve and collect more data (such as FMV), data processing techniques must be able to smartly filter relevant data to pass to the ground within the limited bandwidth available.

5.5.2 Unmanned Ground Systems

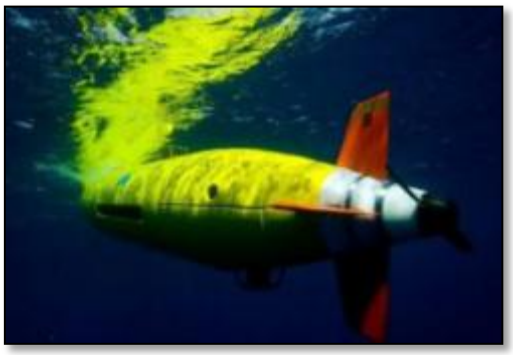
The ability to maneuver effectively in a wide range of environments is a requirement that a UGS must meet. Those environments could include being thrown or launched, climbing hills or stairs, and hopping and landing upright. The technologies for advancing this capability are primarily autonomy, sensors, and avoidance algorithms.

5.5.2.1 Autonomy

The ability of the UGS to navigate autonomously is largely dependent on the accuracy and robustness of its perception system, which seeks to create an accurate model of its environment. Designing a perception system capable of dealing with all types of environments is very challenging with the current technology. To constrain the problem, current state-of-the-art UGS are designed from the ground up to operate within an assumed environment(s). If these assumptions are valid, the UGS often operate effectively. The UGS will fail to operate as intended, however, when circumstances are different from assumed. To alleviate this problem, it is desirable to have a perception system that can adapt to various environments. To be able to adapt, the UGS must understand the context of its environment and recognize when that context changes. One possible method of understanding context is through the classification of video imagery. Once an environment is classified, UGS require perception adjudication that specifically addresses the perceptual needs of the UGS at run-time. A number of factors dictate the perceptual needs of UGS, including mission awareness, environmental complexity, mobility requirements, and the sensor capabilities necessary to build contextual information from the environment. The

3964 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

enabling technology supporting these factors includes hardware and software related to autonomy, communications, power, vision, architecture, warfighter machine interfaces, manipulators, terrain mobility, and payloads.



5.5.2.2 Sensors and Avoidance Algorithms

Although collision avoidance systems on unmanned systems have been tailored for UAS, there is also a great need to apply them to ground systems. Examples of this technology include collision avoidance algorithms, traffic pattern recognition, and navigation. While avoidance systems for UGS may come about from UAS technologies, a good opportunity to leverage developments comes from the auto industry. The auto industry has a much greater ability to apply research and development technology funding with the initial focus on improving safety, and many of these technological developments will apply to making UGS safer as well.

5.5.2.3 Other UGS Technologies to Consider

Other technologies may also give UGS greater flexibility within its intended environment. Interoperability may be a very important consideration to reduce costs and add efficiency, especially as the sensors become more complex. Issues such as dual-use sensors, high/low data, data storage, and secure communication links may all be very important to evaluate. Vehicle-to-vehicle communications have the potential to greatly increase safety by sending and receiving data messages across equipped vehicles and translating the data into warnings to the driver of potential collisions. Several top auto manufacturers are quickly developing prototypes with varying technologies for civil auto applications. These technologies will benefit the civil community through fuel and time savings and improved safety and will certainly have benefits to DoD as well.

5.5.3 Unmanned Maritime Systems

UMS may be used for a variety of purposes. They can ensure security within harbors, scan for problems on a ship hull, sweep an area for mines, secure critical waterways, provide ocean tracking, and more. Because of the operating environment, the technology that allows these capabilities is unique. Like UAS, persistence is a key capability that UMS can provide; however, unlike UAS, UMS allow more than just persistence. For example, the largest issue with UAS is their inability to operate in bad weather or low visibility. UUVs, on the other hand, can operate in poor weather conditions. Therefore, DoD can continuously scan for mine drops or follow an enemy threat such as a submarine. In any case, persistence requires improved power and propulsion systems, autonomy and data processing, improved communication systems, and advanced sensors.

5.5.3.1 Power Systems

Certainly powering for long-term persistence is a large challenge. Having the ability to sprint at high speeds to intercept a target is not the only power requirement. Towing also requires power; for example, the mine warfare mission typically requires a significant tow load — much

3965 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

more than a normal craft's capability. Certain supporting payloads are also very power intensive. A USV carrying other UUVs or USVs would have to recharge or refuel the other payloads, and this requirement would require more power.

5.5.3.2 Autonomy and Data Processing

Like UAS or UGS, UMS can be preprogrammed for certain missions. For example, UUVs can autonomously scan the hull of a ship for threats or other foreign objects within harbor or scan a geospatial area for mines. However, the technology gets more complex as the level of autonomy increases. The appropriate autonomy level plays a key role in persistence during clandestine missions, e.g., the ability to sense and avoid hostile forces and to detect and avoid obstacles such as approaching vessels, fishing nets, or more conventional obstacles like rock formations or coral heads. Autonomy may also play a key role in the capability to diagnose and react in a proportional manner to UMS internal failures (fault management) during long missions, especially in clandestine missions. For these types of missions, the UMS needs the capability to send important, relevant information as needed, such as relaying the track of a detected threat.

Data processing enables the transmission of a reduced amount of data like beam-formed sonar images instead of raw, stave data, without compromising quality. Not only is there a need to use preprocessing to reduce the amount of data transmitted, but also automated target recognition enables target discrimination, i.e., reporting contacts of interest instead of sending entire images for human interpretation.

5.5.3.3 Communication Systems

Communication systems on UMS drive the need for advanced data processing techniques. Undersea C2 limitations preclude teleoperated solutions, and such limitations drive UUV autonomy needs. Bandwidth is much lower with acoustic signals compared to RF signals; therefore, wireless data rates are reduced. In clandestine operations, C2 links must extend over long distances into the undersea environment to provided operators with situational awareness and supervisory control over a UUV.

5.5.3.4 Advanced Sensors

New technologies enable real-time adaptation and optimization of sensor settings and unattended tactical planning for sensor employment according to the environmental conditions. Because a human is not around to recognize that the sensor is not operating optimally, sensors need the capability to adapt to optimize their abilities. In addition, they must improve in other areas:

- ***Marinization.*** Typically most commercial sensors are built for UAS. Their environment is simpler compared to USVs and UUVs. Not only is salt water a problem, but the accelerations and shock from bumps are well above anything experienced by a UA.

3966 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

- ***Built-in test.*** Sensors must have the ability to know and report when they are not working correctly so the control system can take appropriate action.
- ***Data fusion.*** To be truly useful in the future, sensor data output must be standardized for incorporation into a fusion engine providing for a better world view (i.e., understanding of the environment around the unmanned system).
- ***Additional capability.*** Sensors must allow for faster operation (i.e., as speed of a USV increases, cameras and radars must be able to see further and clearer to determine the proper course of action so the vehicle has time to react).

Sensors must continue to be developed and improved to gain even more capability and robustness in a maritime environment.

5.6 Way Ahead

To operate within the existing regulatory environment, programs must comply with existing policy framework or get policy waivers because policies tailored to unmanned systems are still in development. Regulatory and cultural hurdles must be carefully considered early in system development. In this paradigm, technology development and tests will help shape the appropriate requirements, standards, and regulations. Industry will help frame what is possible as the "state of the art," and programs will define what is fiscally responsible. Once the standards and regulations are complete, PORs can then create requirements for their systems with a complete set of expectations.

5.7 Case Study: Air: Airworthiness and GBSAA

Services programs and CCDRs that require UAS must define the types of airspace they require for their missions. The CONOPS should define the operating environment, considering the NAS for training before deploying overseas in a foreign airspace. Two important factors, although not the only factors, for UAS flights in the NAS are the airworthiness of the vehicle and the SAA solution to comply with FAR or COA requirements. Below, we quickly examine these factors in a case study of the Army Gray Eagle at Fort Hood, Texas. The Gray Eagle currently requires a COA to transit from Joint use Class D airspace to restricted airspace a short distance away.

Like manned systems, the Gray Eagle vehicle must be certified as airworthy and properly equipped to fly in the intended airspace. The aircraft structure, propulsion system, control redundancies, software, and control links must all be certified to a certain standard defined by the Service's technical airworthiness authority (TAA). However, the Army has determined that certification costs are prohibitively expensive to certify the Gray Eagle to manned aircraft

3967 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

standards. Therefore, the Army TAA takes into account the potential risk of a failure and the population density below the intended flight path, which would cross over a road. To minimize risk to people and property on the ground, the Gray Eagle will fly perpendicular to the road and take other similar precautions.

The Army has a clear understanding of the airspace the UAS must transit, equipage requirements for that airspace, normal aircraft traffic patterns, surrounding terrain, and other potential hazards to accomplish its training mission. The Army decides that GBSAA is the chosen SAA solution based on mission requirements and costs. The GBSAA radars monitor the airspace for potential conflicting traffic, and algorithms assess the potential for conflicts and suggest heading changes to the operator to maintain separation.

The combination of these efforts allows the Army to confidently navigate the airspace safely with regard to other airspace users as well as people and property on the ground. This solution provides the capability to accomplish the training mission without incurring high costs such as transiting the entire unit to another location.

5.8 Summary

Technology is evolving rapidly, and this fast evolution is challenging regulatory authorities to keep pace with needed rules and regulations as well as challenging military departments to keep costs down when abiding by DoD acquisition and management processes. Every aspect of the operating environment, including the physical and regulatory, should be kept in mind at every stage of the acquisition life cycle. Guidance is currently available from each Military Department although the requirements and standards must still be developed.

Unmanned systems are ideally suited to increase the envelope for the physical environment. They are often built with the intent of putting them in harm's way and avoiding risk to a pilot, operator, or controller. The timeline in Figure 33 shows the technical path toward successful increases in capability across the domains for the next 25 years.

3969 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

6 Logistics and Sustainment

6.1 Current Sustainment Environment

The rapid development and fielding of large numbers and types of unmanned systems present DoD with a significant sustainment challenge. Reliance on joint operations and multinational coalitions further complicates that sustainment challenge. Joint mission requirements need matching logistics capabilities that meet the specific mission requirements of the CCDR.

Evolving requirements often force premature system redesign efforts to meet emerging warfighter needs. Rapidly evolving technology and economic conditions affect the requirement and the ability of unmanned systems to meet stated reliability, maintainability, and affordability requirements. Original equipment manufacturer (OEM) assertions of proprietary interests complicate organic support. As budget pressures increase, programs must develop more cost-effective sustainment solutions. The transition from supporting the warfighters' immediate capability requirements to creating an affordable, long-term sustainment environment will require a flexible blend of OEM and organic support to meet logistics support objectives.

6.2 Problem Statement

The first generation of fielded unmanned systems was focused on the rapid delivery of immediate capability to the warfighter. Because of the need to rapidly develop and field these initial capabilities, long-term sustainability planning has often occurred late in the development cycle. Many programs have been procured as vertically integrated, vendor-propriety solutions relying on a single prime contractor who was often held accountable to meet many criteria, including a compressed delivery schedule. These rapidly fielded programs are often immature in terms of reliability and supportability and are heavily reliant on contractor logistics support (CLS). In most cases, unmanned systems are no different from manned platforms and require investments in reliability and maintainability to provide availability at an affordable cost. However, reliability, maintainability, and lifecycle costs have been secondary considerations, and early application of reliability and maintainability engineering activities to the design has been neglected. As programs plan for long-term sustainment, they must establish lifecycle sustainment strategies that can cost-effectively meet documented warfighter requirements and comply with statutory requirements and DoD policies.

3970 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

6.3 Challenges to Logistics and Sustainment

The need to quickly field unmanned capability led to shortcomings in the area of logistics and sustainment planning and implementation. Challenges include

- Sustaining non-PORs
- Limited RAM data
- Delayed core logistics capability requirements
- Transition from CLS for Life to Organic capabilities
- Immature or lack of lifecycle sustainment planning

6.3.1 Sustaining Non-PORs

Programs initially fielded as user operational evaluation systems or as rapid acquisitions in response to JUONs have since transitioned to PORs that provide enduring warfighting capabilities. Many involve procurement quantities of hundreds of units that will be sustained for the foreseeable future. The Services have focused on "getting product out the door," rather than maturing and improving sustainability within systems because of the urgent goal to meet immediate warfighter needs with unmanned systems capabilities. The programs often have not developed the data strategies to support the system for the long term, including procuring failure and product support usage data. The Services have met the needs of the warfighter by fielding developmental versions of the PORs as quick reaction capabilities, fielding non-POR sensor and weapons capabilities on POR platforms, and fielding multiple POR low-rate production units prior to completion of the initial operational test and evaluation (IOT&E) and formal declaration of IOC.

The Services have also developed innovative, and sometimes ad hoc, logistics concepts to support near-term in-theater warfighter readiness. For instance, in 2006, the Army Materiel Command chartered the RS-JPO to provide in-theater support via the Joint Robotics Repair Facility (JRRF) and the Joint Robotic Repair Detachments (JRRDs). JRRF provides a one-stop shop for fielding, sustainment, training assessment, and asset accountability. It also provides support, e.g., operational instruction, preventative maintenance checks, services, and troubleshooting. The JRRDs, established in Kuwait and Afghanistan, fill an Army maintenance capability gap created by the acquisition and deployment of commercial off-the-shelf (COTS) robotic systems in theater. These organizations operate outside the standard Army logistics system and force structure to provide training and to issue and repair robotic equipment. The facilities are staffed with a mix of Government personnel and contractors.

3971 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

6.3.2 Limited RAM Data

Much of the unmanned systems capabilities were delivered with large numbers of developmental and low-rate production assets that were not fully matured or proven to meet the system's RAM requirements. The lack of proven reliability creates a challenge to long-term system availability and affordability because reliability is typically the single largest design-controllable driver of operations and sustainment costs. While providing a tremendous capability to the warfighter, when IOT&E does occur, systems often do not meet their operational sustainment thresholds and are deemed not suitable.

6.3.3 Delayed Core Logistics Capability Requirements

The rush to deliver these critical capabilities to the field led to a reliance on the OEM to satisfy sustainment requirements. Prime contractors have been responsible to provide CLS to ensure the operational readiness of their systems in the field. In many cases, little organic maintenance capability at the military organizational and intermediate (field) level has been established. Program offices have relied on the capacity of the prime contractors' production lines to satisfy depot maintenance requirements. The delay in the establishment of organic depot capabilities sometimes put programs at odds with statutory requirements. Several programs have begun the transition from contractor support to an organic capability. However, contractor assertions of proprietary technical data rights,[74] investment costs for support equipment and facilities, parts obsolescence, and frequent software upgrades create challenges to establishing depot capability in the near term. In an effort to create organic maintenance efficiencies and commonalities between the programs, the Services have begun to work together to identify potential synergies in establishing common sustainment concepts and capabilities. An FY2011 UAS Organic Depot Study recommended the establishment of repair capabilities at a limited number of depots based on major subsystems to take advantage of existing depot capabilities and capacity (see Figure 35 in 6.7.1). The Joint Logistics Board endorsed the workload assignment consolidations and directed that Air Force avionics, ground electronic, software, and sensor workloads be further evaluated for potential consolidation.

6.3.4 Transition from CLS for Life to Organic Capabilities

For UAS, the same FoS was often selected to meet the requirements for ISR and weapons platforms of different Services; therefore, a large degree of commonality exists among the various platforms and sensors. However, because of the initial strategy of using the prime contractor for CLS for life to sustain rapidly deployed and evolving capabilities, the various program offices are just beginning to recognize and take advantage of commonalities by establishing common logistics infrastructures to reduce investment costs as they develop plans to transition to organic support late in the development cycles.

Contracts for CLS, in many cases, have not been performance based, i.e., requiring specified levels of readiness, but rather cost-plus-award-fee arrangements providing flexibility to respond to changes in requirements and OPTEMPO. While these arrangements provide an

[74] 10 USC 2320 provides that in the case of an item developed by a contractor or subcontractor exclusively at private expense, the contractor or subcontractor may restrict the right of the United States to release or disclose technical data to persons outside the Government. The statute further states that these restrictions do not apply to technical data that are necessary for operation, maintenance, installation, or training.

3972 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

immediate advantage to quickly field warfighter operational capability, more affordable sustainment solutions are required as fleet sizes have grown.

6.3.5 Immature or Lack of Lifecycle Sustainment Planning

Fielded unmanned systems are frequently not managed or maintained as other platforms are within the inventory. For instance, with Army UGS, the operational urgency and uniqueness of these platforms required a nonstandard approach in integrating these technologies into the force. This understandable and needed deviation created, as a byproduct, a parallel management system that bypassed many established processes and procedures. The RS-JPO sustainment strategy for the family of robots includes improvements and upgrades to current platforms with the latest technologies. Due to the drawdown from theater, RS-JPO is developing a responsible drawdown strategy that includes long-term storage and future disposition of robotic systems.

The Army lacks adequate maintenance doctrine to address the technologies incorporated into robotic systems. Robotic maintenance doctrine has not been delineated in Army doctrine. Only a small group of operators and personnel within the Army working in the development, testing, and acquisition of robotic technologies is well acquainted and/or understand the impact of these technologies. RS-JPO initiated efforts to improve the maintenance strategy by improving databases and how data are analyzed, decreasing top sustainment parts cost drivers, and outsourcing repairable parts. By improving the way data are collected and analyzed in the Cataloging Ordering Logistics Tracking System, JRRF hopes to identify and increase MTBF and identify systemic parts problems to reduce the number of parts consumed. Also RS-JPO is currently working with the OEMs to analyze the repair-versus-replace cost of their top sustainment parts cost drivers to determine whether the return maintenance actions are being accomplished efficiently. Future plans also include the possible outsourcing of parts repairs to a non-OEM contractor. JRRF continues to develop and refine repair processes and serve as the center for technician support for all the detachments and training sites.

Multiple challenges exist for sustainment due to the many different configurations of nonstandard equipment (NSE). The optimum goal is to have modularity across platforms for plug-and-play adaptability. This approach will reduce the number of required repair parts and allow plug-and-play payload options to fulfill multiple capability requirements. This effort will also maximize the life of the current fleet and save a substantial amount of money in repairs and spare part purchases.

6.4 The Way Ahead

For unmanned systems to move from an environment of rapid development and fielding to an environment of long-term sustainment, programs must take a lifecycle management approach. Affordable lifecycle sustainment solutions that meet the warfighter's threshold requirements must be generated to maintain the capabilities of the first generation of unmanned systems over the foreseeable future. As new unmanned systems and capabilities are developed, new programs must apply lessons learned to ensure long-term sustainability is addressed early in the development process.

In September of 2011, USD(AT&L) directed that sustainment plans be developed for all unmanned acquisition programs and be reviewed for improved affordability and effectiveness.

3973 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Lifecycle logistics planning and analysis execution is important from the acquisition phase through operations to the retirement phases of the weapon system life cycle. Cross-functional planning and integration are essential to ensure that supportability requirements are addressed comprehensively and consistently with cost, performance, and schedule during the life cycle. The objective is operational effectiveness through an affordable, effective support strategy that meets goals for optimum readiness and facilitates iterative technology enhancements during the weapon system life cycle. See Figure 34.

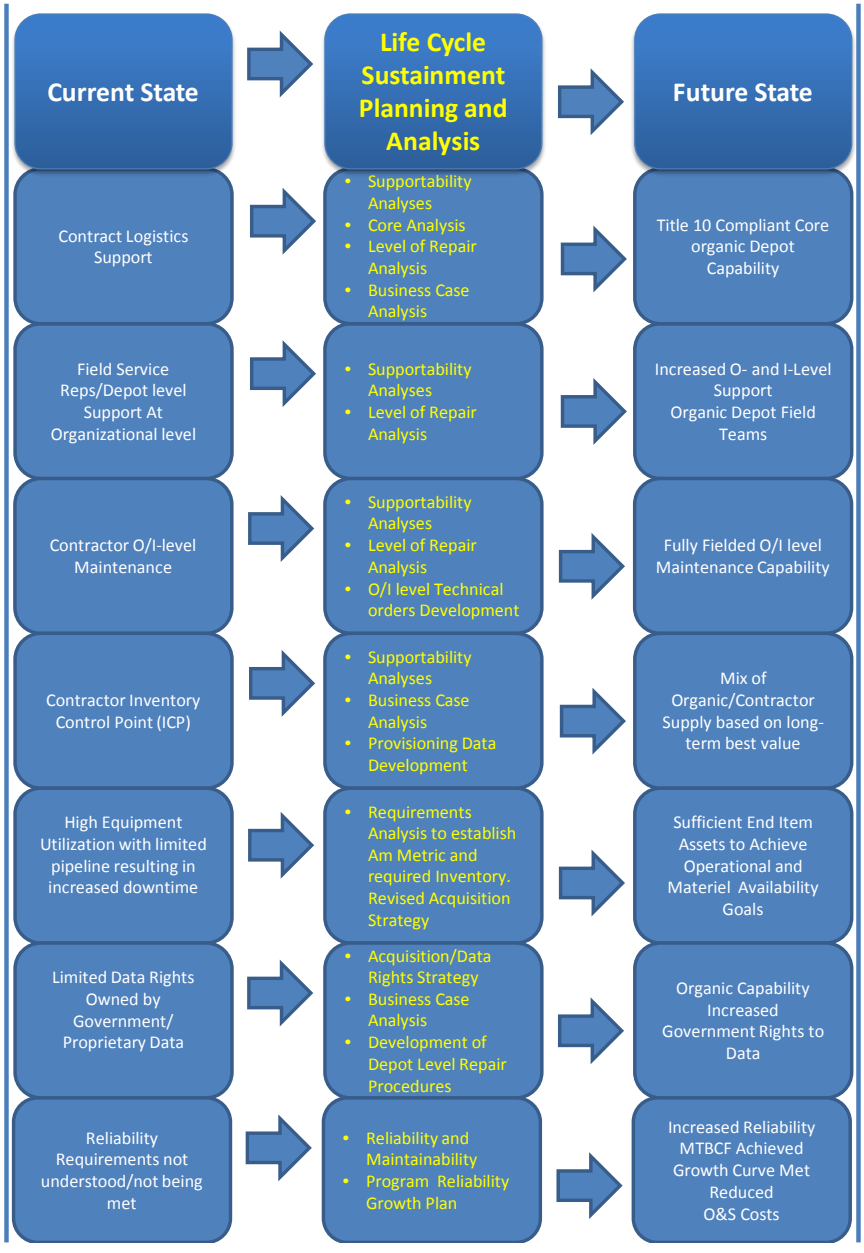

Figure 34. Lifecycle Sustainment Planning Analysis Way Ahead

3974 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

6.5 Planning for Organic Depot Maintenance

Central to sustainment planning and execution is the concept of core depot-level maintenance capabilities. First codified in 1984, the current statute[75] states, "It is essential for the national defense that the Department of Defense maintain a core logistics capability that is Government-owned and Government-operated (including Government personnel and Government-owned and Government-operated equipment and facilities) to ensure a ready and controlled source of technical competence and resources necessary to ensure effective and timely response to a mobilization, national defense contingency situations, and other emergency requirements."

The National Defense Authorization Act (NDAA) for FY2012, as further amended in the FY2013 NDAA, introduced several new provisions of law relating to the identification and implementation of core logistics capabilities that affect the sustainment of UAS. The law now specifically requires a determination of the applicability of core logistics requirements by Milestone A and an estimate of core logistics capabilities and sustaining workloads by Milestone B. The identification of core capability requirements and sustaining workloads is now a three-stage process linked to the acquisition cycle. The Milestone Decision Authority (MDA) must now certify pursuant to 10 U.S.C. 2366a(a)(4), "that a determination of applicability of core depot-level maintenance and repair capabilities requirements has been made," prior to Milestone A approval.[76] Milestone B approval may not be granted until the MDA certifies, "An estimate has been made of the requirements for core depot-level maintenance and repair capabilities…and the associated sustaining workloads to support such requirements."[77] Additionally, "Prior to entering into a contract for low-rate initial production of a major defense acquisition program, the Secretary of Defense shall ensure that the detailed requirements for core logistics capabilities…and associated workloads required to support such requirements have been defined." This three-stage process is designed to identify organic depot-level maintenance requirements early in the acquisition cycle to reduce the necessity for interim CLS and to allow for the timely establishment of organic capabilities. The determination that a function is core requires that government-owned and government-operated depot-level maintenance and repair capabilities and capacity, including the facilities, equipment, associated logistics capabilities, technical data, and trained personnel, shall be established not later than four years after a weapon system or item of military equipment achieved IOC or is fielded in support of operations.[78]

The early identification of core requirements and sustaining workloads will drive programs to identify and acquire data required to establish repair capabilities early in the acquisition process. DoD must also be ready to challenge assertions that unmanned systems were developed exclusively at private expense, or at a minimum be prepared to aggressively assert its "Government purpose rights" (under the provisions of 10 USC 2320) to the technical data required to maintain these systems.[79]

3975 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

6.6 Sustainment Metrics and Performance-Based Logistics

Recent JCIDS guidance requires the establishment of a Sustainment KPP for all ACAT 1 programs in the capability development document and Capabilities Production Documents (CPDs) for the system.[80] ACAT II and below programs with materiel solutions are required to include the Sustainment KPP or sponsor-defined sustainment metrics. The Sustainment KPP is stated as a Materiel Availability threshold and objective and is supported by key system attributes for reliability and for Operations and Support (O&S) costs. Establishing these metrics early and tracking them throughout the life cycle of the program will help ensure that the programs can meet the warfighter's requirements at an affordable price. The flowdown of these metrics into performance-based logistics strategies to achieve operational effectiveness and system affordability is the preferred approach to systems support.[81]

Establishment of rigorous *reliability growth* programs to ensure that programs are meeting reliability thresholds has great potential to enhance the long-term affordability and availability of unmanned systems. Incorporating *design* features to enhance maintainability and supportability into future UAS has the potential to greatly increase readiness and lower O&S costs. Incorporating modularity and common interfaces that can accommodate integration of new sensor, weapons, and communication capabilities without requiring major platform redesigns and retrofits can potentially improve maintainability by simplifying the fault isolation, removal, and replacement of subsystems. In-flight diagnostic and prognostic technologies have the potential to improve repair turnaround and improve readiness. As the unmanned systems portfolios mature, responsible program executive offices (PEOs) and program offices can create opportunities for efficiencies by adopting policies and processes that encourage the use of common components and configuration elements, such as batteries, fasteners, electrical distribution panels, and support equipment. Commonality creates opportunities for common supply chains, sources of repair, and other product support elements.

6.7 Joint Logistics Integration

6.7.1 Unmanned Aircraft Systems

As the sustainment of UAS becomes more institutionalized within the organic support infrastructures for maintenance, supply, and transportation, the accomplishment of much of the field- and depot-level maintenance will transition from CLS to the Government and military. Because of similar platform characteristics, subsystems, and manufacturing and repair processes, there is great potential for UAS programs to team together to reduce investments and operations and maintenance costs. The use of tools such as public/private partnerships (PPPs) and performance-based logistics contracts should be explored as methods to reduce sustainment and infrastructure costs. Agreements across different programs and Services can also reduce the costs of establishing organic repair capabilities and incentivize increases in systems reliability. As a result of these efforts, overall O&S costs can be reduced.

To facilitate the identification of opportunities to reduce overall investment and O&S costs, the UAS Task Force has established a Logistics and Sustainment IPT with the Services. In

FY2011, a depot WG was established to recommend depot sources of repair for UAS major subsystems. The group recommended the establishment of depot repair capabilities at a limited number of depots based on major subsystems to take advantage of existing depot capabilities and capacity (see Figure 35). The Joint Logistics Board endorsed the workload assignment consolidations and directed that Air Force avionics, ground electronic, software, and sensor workloads be further evaluated for potential consolidation. The recommendations resulted in rational depot source of repair assignments for UAS core workloads and generated large cost avoidances and savings.

Figure 35. Organic Depot Maintenance Sources of Repair Approved Consolidations

In FY2012, the Logistics and Sustainment IPT met to create a forum to discuss lessons learned and to foster sustainment synergies. The IPT has identified potentially high payoff strategies of creating partnerships with industry to support families of components, such as sensors and communication links common across the Services. The UAS programs are researching opportunities to use existing manned aircraft capabilities to sustain similar UAS components. The Air Force's Reaper program and the Army's Gray Eagle program will use the Navy's Fleet Repair Center Southeast, Jacksonville, Florida, repair capability for H60 helicopter MTS-A sensors to repair their MTS-B sensors.

3977 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

6.7.2 Unmanned Maritime Systems

The Navy is currently supporting UMS through a combination of OEM and organic support. In the next few years, the sustainment strategy and infrastructure for UMS must be formalized and standardized to gain better control of the supportability resources and become more responsive and effective. The quantities of USVs and UUVs being developed and fielded in the next decade demand that attention be given to effective system sustainment. An organic support infrastructure for configuration control, supply support, maintenance, storage, and transportation is essential to bring efficiencies and cost effectiveness to these critically important systems. A planning yard should be established for UMS.

6.7.3 Unmanned Ground Systems

For UGS, due to the tremendous amount of dollars invested into NSE to meet the warfighter capability gap for the current conflict, the Army's Capabilities Development for Rapid Transition process categorized NSE robots into three categories: 1) recommend POR, 2) retain to support in theater, and 3) terminate. The majority of the NSE robots fall into category 2. A significant quantity of NSE robotic systems has been purchased and is being maintained using other contingency operations dollars. These NSE robots have proven to provide a needed capability to the warfighter and have saved lives. Also, these NSE robotic systems provide some of the capabilities outlined in the documents of developing PORs that meet current and future operational commander's capability requirements, but these PORs are not scheduled to be fielded until FY2015 and beyond. The strategy is to utilize some of the NSE robots as a bridging capability to the PORs until the PORs are fielded, store them for future contingencies, or utilize them as training aids. Nevertheless, these NSE robots still require a sustainment package that can be provided by JRRF or the OEM.

3978 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

7 Training

7.1 The Need to Train

Training is a critical link in delivering warfighter capability. DoD can acquire and deliver the most technologically advanced equipment, but if the operators, maintainers, leaders, planners, users, and support personnel are not properly trained on the equipment or do not have a thorough understanding of its CONEMP, the advantages offered by this warfighting capability will be lost through its misapplication. A study by the Defense Science Board found that "U.S. armed forces have a training superiority that complements their technological superiority."[82] The report points out, however, that this superiority can be eroded if the acquisition process does not properly integrate training into equipment development, testing, and fielding. The criticality of acquisition and training integration is emphasized by the requirement for acquisition program managers to "work with the training community to develop options for individual, collective, and Joint training" as part of the acquisition process.[83] The report also emphasizes that failure to deliver adequate training venues, where needed, will negate technical superiorities of hardware. Operators, maintainers, users, support personnel, and leaders must, therefore, be properly trained at the appropriate levels and intervals throughout their careers using the optimum mix of live, virtual, and constructive or blended reality training domains so they can use equipment effectively and to its full design capability. This chapter describes the current state of training for unmanned systems, some of the challenges involved, and the way ahead.

7.2 Problem Statement

Unmanned systems have been a warfighting success story, but work must still be accomplished in the institutionalized training environment. As operations in Afghanistan draw down and decisions are made about which systems transfer to a peacetime footing, the Services will have to make serious decisions about training. These decisions will not be limited to simply stating recurring training requirements. Rather, the details of how the training will be implemented must be planned and weighed so that every training opportunity is maximized to offset its incurred costs. At play will be cultural and political realities; interacting dynamics of technology, policy, and regulation; and fiscal constraints. Failure to meet the training challenges will result in a loss of combat-gained experience and an inability to effectively employ these systems in the future.

7.3 Challenges to Training

Even with the success unmanned systems demonstrated on the battlefield, DoD faces challenges in training. These challenges, as discussed in 7.4, relate not only to the types of unmanned systems (e.g., UAS, UGS, UMS), but also to acquisition, regulations, technology, manpower and other assets, and policy and documentation. This discussion is by no means exhaustive or in any particular order of precedence. Furthermore, DoD fully expects that as new generations of unmanned systems develop, the variety of missions they perform expands, and

[82] Report of the Defense Science Board Task Force on Training Superiority & Training Surprise, OUSD(AT&L), Washington, DC, January 2001.
[83] DoDI 5000.02 Operation of the Defense Acquisition System, 8 December 2008, p.61.

3979 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

priorities change based on circumstances such as wartime, OPTEMPO, NAS restrictions, new challenges will arise.

7.4 Current Training Environment

Today's training environment for unmanned systems is similar to that characterized for logistics and sustainment, i.e., one of playing catch-up, in this case, to provide training support for the rapid fielding of unmanned systems. The term "disruptive technology" was coined by Clayton Christenson in 1995 to describe a situation where a technology introduces new priorities and value structures requiring significant structural adjustments to processes, organizations, and operational paradigms. The rapid development and fielding of large numbers and types of unmanned systems to meet expanding contingency needs is an example of a disruptive technology, which has resulted in significant challenges for the training community. The challenges presented by sheer unmanned systems numbers, diversity, and rapid fielding are complicated by the imminent drawdown of forces in theater and their return to a peacetime footing with a more stringent regulatory environment.

Improvements in joint operations integration, both at the individual and unit levels, are necessary to be able to employ combat capability synergistically:

- Operators must receive tailored training specific enough to support unique Service mission sets, yet broad enough to allow operators to integrate and contribute in a coalition environment.
- Training programs must adequately encompass initial qualification and proficiency/refresher training while also providing room to accommodate growth as technology and TTPs improve and evolve.
- Training programs must be integrated into the institutional base.

These challenges include such things as availability of resources, policy, and regulation. DoD is cognizant of these challenges and is making progress toward meeting them. In the future, the use of common equipment may also significantly reduce overall program costs and time to train.

7.4.1 Unmanned Aircraft Systems

UAS are fielded by all four Services. UAS training has undoubtedly received more attention than UGS and UMS training. Service training programs are at different stages of maturity; however, as unmanned systems have matured, so too have the Service training programs. In an effort to establish minimum levels of training across the Services, the Joint Staff developed CJCSI 3255.01, which serves as the foundational crewmember training enabler with the FAA toward UAS integration into the NAS.[84] To achieve initial manning levels and arrive at a steady-state throughput, the Services have used varying mixes of organic and nonorganic UAS training, a variety of approaches for the different groups of UAS, and various personnel strategies.

[84] CJCSI 3255.01, Joint Unmanned Aircraft Systems Minimum Training Standards.

3980 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

7.4.1.1 *Army*

The Army architecture for its Group 3 and above UAS operations includes an aircraft operator and a payload operator. The Army operates and maintains its RQ-7 Shadows, MQ-5 Hunters, and MQ-1C Gray Eagles. The 2nd Battalion, 13th Aviation Regiment (2–13th Aviation), formerly Army UAS Training Battalion (UASTB), located at Fort Huachuca, Arizona, conducts initial entry and military occupational specialty (MOS) training for all operators, maintainers, and leaders on Group 3 and above UAS. Operators attend a two-phase training program (see Figure 36) and receive a 15W MOS plus an additional skill identifier (ASI) for the aircraft they are qualified to operate. Maintainers attend a 17-week common UAS repairer course graduating with a 15E MOS, which qualifies them to maintain the Shadow. Additional courses and skill identifiers are required for qualification in Hunter and Gray Eagle maintenance. Additionally, 2-13th Aviation supports the Joint community by training Marine Corps and Navy UAS personnel. In FY2012, they trained more than 2,100 UAS personnel.[85]

The Raven is the Army's primary SUAS. Ravens are lightweight, man-portable, and operated and maintained by a single soldier. The Army's Maneuver Center of Excellence at Fort Benning, Georgia, currently conducts all Army Raven UAS training. As of 1 October 2012, the Army has transitioned to a SUAS Master Trainer program to train experienced operators at Fort Benning. These Master Trainers then return to their respective units to train SUAS operators at home station; this approach reduces the impact to the unit and enhances training flexibility. Uniformed instructor mobile training teams that deploy to units to deliver the syllabus are used to supplement training needs. Training is provided primarily to enlisted soldiers, but officers are also trained. Upon completion of the course, personnel are qualified to program, launch, fly, retrieve, and maintain Ravens. Qualification does not result, however, in the award of an MOS or Specialty Identifier.

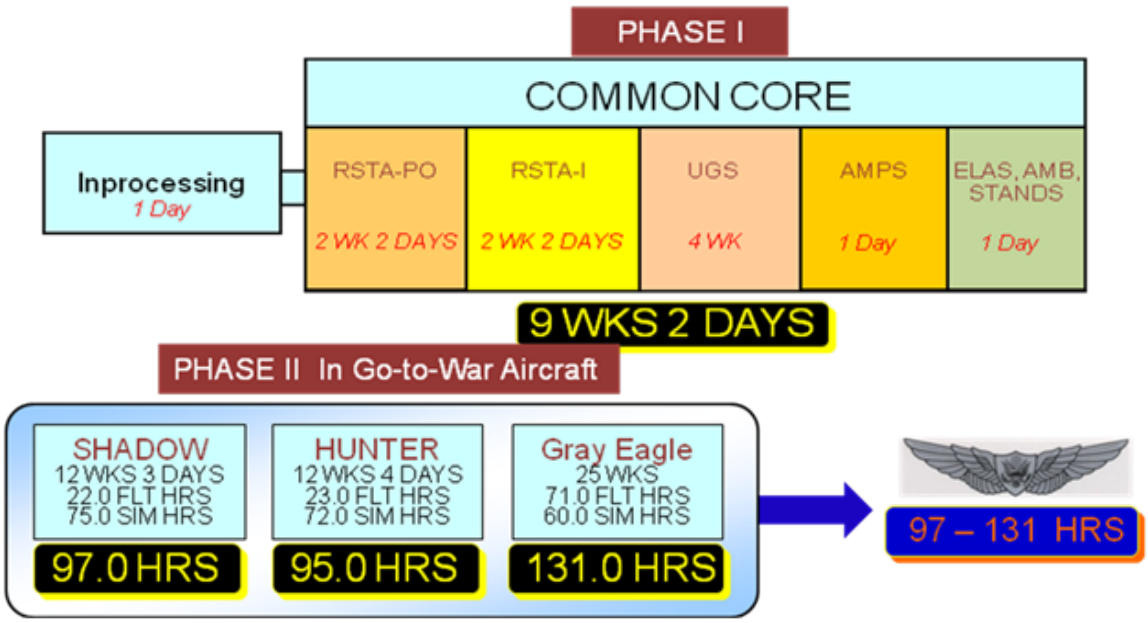

Figure 36. Army Group 3 and Above UAS Operator Training Flow

3981 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

7.4.1.2 *Marine Corps*

The Marine Corps uses a three-person crew for its RQ-7B Shadow training. The crew consists of an unmanned aircraft commander (UAC), an air vehicle operator (AVO), and a mission payload operator (MPO). RQ-21A Small Tactical Unmanned Aircraft Systems (STUAS) are crewed by a UAC and an AVO, who performs the MPO function as well. UACs are officers, while both AVOs and MPOs are enlisted positions. Currently, Marine Unmanned Aerial Vehicle Squadron (VMU) officers are sourced from the existing pool of qualified aviation officers; however, with the establishment of the VMU Officer Primary Military Occupational Specialty (PMOS), new second lieutenants will begin to be qualified as UACs. This dual sourcing strategy will continue until grade shaping of the MOS is achieved. AVOs and MPOs are sourced as entry-level positions, and each is also assigned a unique UAS MOS identifier.

The Marine Corps utilizes Army, Navy, and Air Force schools to train its VMU personnel, including maintenance personnel. The flow for Marine Corps Group 3 training is depicted in Figure 37. The Marine Corps is currently exploring the feasibility of standing up a UAS schoolhouse to standardize training for its RQ-7B and RQ-21A UACs, operators, and maintainers. This schoolhouse will build on joint training primary schools and maximize the use of simulation.

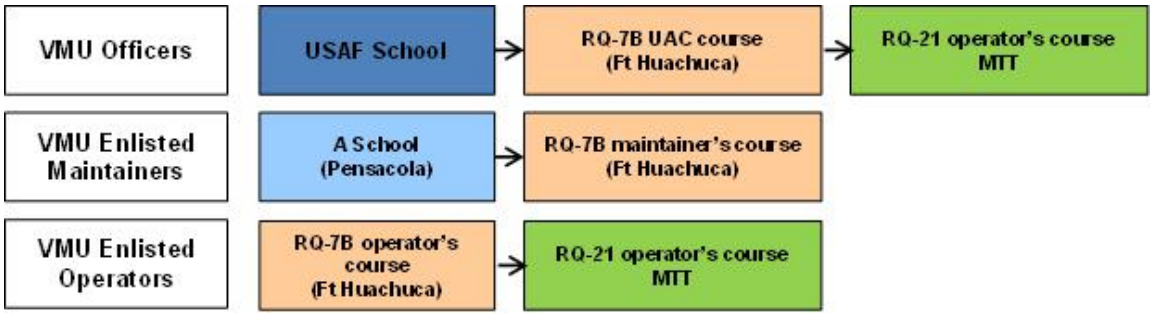

Figure 37. Current Marine Corps Group 3 UAS Operator Training Flow

In July 2012, the Marine Corps stood up a Group 1 SUAS training activity at Camp Lejeune, North Carolina, to provide standardized non-MOS training for enlisted Marine Corps operators of SUAS. One of the goals of this schoolhouse is to relieve the line units from the burdens of providing initial SUAS training for their operators. By providing a centralized schoolhouse co-located with 2nd Marine Division, efficiencies in training and logistics have been achieved. A similar SUAS training activity is planned for Camp Pendleton, California, in support of 1st Marine Division.

7.4.1.3 *Air Force*

The Air Force classifies its Groups 4 and 5 UAS (MQ-1 Predator, MQ-9 Reaper, and RQ-4 Global Hawk) as Remotely Piloted Aircraft (RPA). RPA pilot and sensor operator aircrews are formally trained to operate the aircraft. Officer RPA pilots are sourced from the current rated pilot community or through the newly established Undergraduate RPA Training (URT) program, similar to Specialized Undergraduate Pilot Training (SUPT) program for manned aircraft. URT is another dual accession strategy to reach initial USAF RPA manning requirements. Sensor operators are enlisted airmen sourced similarly to pilots, some from current intelligence career

3982 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

fields and others through the newly created RPA sensor operator career field. The Air Force created new career fields and associated specialty codes for both its new rated RPA pilots and sensor operators. The training flow for these positions is depicted in Figure 38 (NOTE: The formal training unit for the Global Hawk is at Beale AFB, California.)

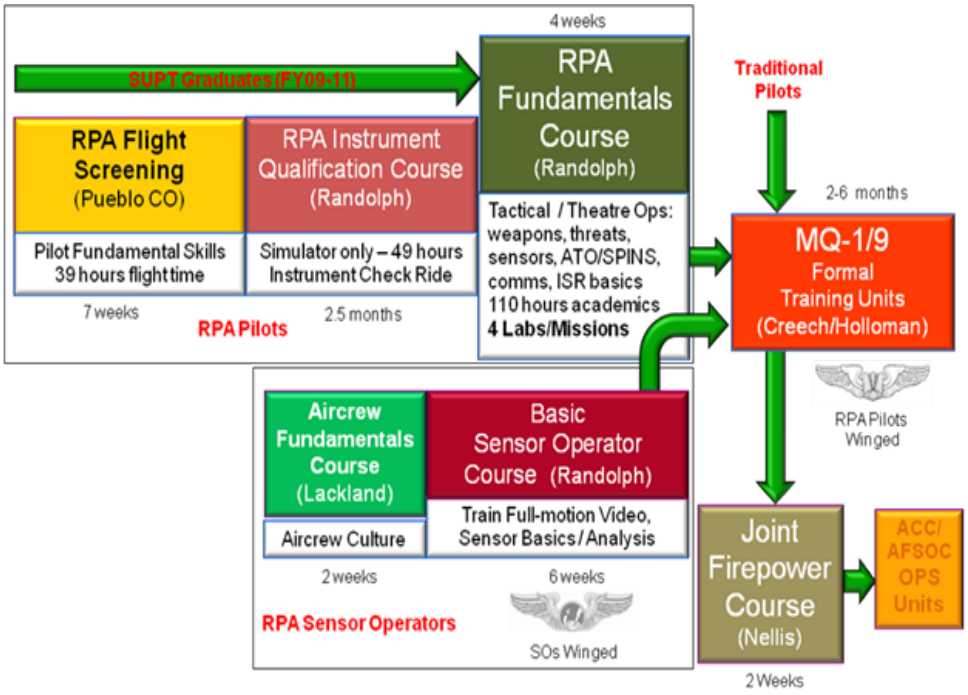

Figure 38. Air Force MQ-1/9 Pilot & Sensor Operator Training Flow

The Air Force has also created a Mission Intelligence Coordinator position to manage real-time/near-real-time intelligence information available to MQ-1/9 RPA pilots and/or sensor operators. Mission intelligence coordinators are sourced primarily from existing squadron intelligence positions and intelligence officer positions. Candidates undergo an initial qualification training course at either Creech AFB, Nevada, or March Air Reserve Base, California, and further mission qualification training at a squadron to attain mission-ready status.

Air Force RPA maintenance training is accomplished at three Air Force skill levels. RPA maintenance fundamentals are taught at the maintenance school at Sheppard AFB, Texas. Following RPA training at Sheppard AFB, initial and advanced skills maintenance training occurs at the operational RPA squadron.

The Air Force classifies its Groups 1 to 3 UAS, such as the Raven, Scan Eagle, and Shadow, as SUAS. They are operated by qualified SUAS operators, primarily enlisted airmen. These SUAS operators attend a formal, 10-day training course approved by Air Force Special Operations Command and conducted by Det 1, 371 SOCTS at the Eglin Range Complex in Florida. Curriculum has been developed and approved for the RQ-11B and is in development for the RQ-20A. SUAS operators are interchangeably qualified as vehicle operators and mission operators, the two crew positions required to operate the system. Qualification as an SUAS operator does not result, however, in the award of an Air Force Specialty Code or Special Experience Identifier.

3983 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

7.4.1.4 *Navy*

While the formal deliberative process for developing training to support emerging large-scale Navy PORs is in the infancy stage, the Navy has the advantage of drawing on lessons learned from the other Services. Current training during system development for PORs and rapid deployment capability efforts is being supported and provided by the associated program offices through contractor arrangements.

The Navy recently opened up a MQ-8 Fire Scout operator and maintainer training center at Naval Air Station Jacksonville. The aircraft and personnel are dual qualified in SH-60 Seahawks and assigned to mixed aviation squadrons containing both Seahawks and Fire Scouts. A similar organizational and basing construct is being examined for the MQ-4 Triton, the UAS complement for the Navy's fleet of P-3/8 aircraft to conduct ISR missions. Triton is currently operated at a demonstration level with training of initial operational evaluation crews slotted for late FY2014 followed a year later by initial cadre training. In June 2010, the Navy and Air Force signed a Triton and Global Hawk synergy memoranda of agreement (MOA) that specifies Navy and Air Force WGs to "Identify and incorporate every appropriate synergy in basing, maintenance, aircraft C2, training, logistics, and data requirements for processing, exploitation, and dissemination (PED) functions."[86]

Viable long-term training solutions for Navy systems are currently being developed within the framework of the basic UAS qualification standards outlined in the CJCSI 3255.01 and the Naval Education and Training Command Course Development and Revision Process.

7.4.1.5 *Continuation and Joint Training*

The focus of Service training efforts and strategy thus far has centered on developing initial skill sets and qualifying personnel to man a rapidly increasing UAS fleet. How to maintain and advance these skill sets through continuation training and education at the individual, crew, and collective levels has been largely overshadowed by the contingency environment. While Services have established currency requirements for their operators, currency is typically maintained through real-world operations rather than in a training environment. Furthermore, additional challenges impact domestic training. These challenges are being mitigated largely by the use of simulators and surrogates, but the full mix and balance of the live, virtual, and constructive domains and blended reality must be identified for the future.

Given that individual, crew, and collective continuation training constitutes the majority of training requirements and activity, the Services will need to continue efforts in these areas. These training programs are necessary to prepare operators for joint training and pre-deployment exercises.

While surrogates and virtual substitutes do address some challenges, the lack of home station UAS training opportunities and codified TTPs can limit the training experience of units preparing for deployment into theater. For example, combat training centers have observed units that were not adequately trained in UAS operations at home station prior to capstone training

[86] Memorandum of Agreement between Broad Area Maritime Surveillance (BAMS) and the RQ-4 Global Hawk system, signed 12 June 2010

3984 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

exercises. Such units routinely receive UAS hands-on immersion training following deployment into theater during mission execution.

Attempts are being made to incorporate unmanned systems into joint and multinational exercises at every level. As a high-demand/low-density asset, live unmanned systems are often unavailable for exercises and pre-deployment training. The use of manned surrogate platforms to replicate aspects of unmanned platform behavior, such as FMV feeds, is common and useful in ensuring the exercise participants are trained and familiar with unmanned systems capabilities when deployed. Additionally, exercise and pre-deployment training scenarios use computer-generated, simulated video feeds to support joint exercises and to ensure warfighters are able to incorporate unmanned systems into their training even when actual systems are not available.

7.4.2 Unmanned Ground Systems

The Army provides UGS training through the RS JPO. Headquartered in Warren, Michigan, the RS JPO's training mission is twofold: 1) to develop, integrate, and manage UGS training operations, requirements, plans, and products through partnerships with organizations and entities internal and external to the RS JPO and 2) to execute joint functional operator and technical training for COTS and POR systems to support force capability generation and unit resetting through mobile training teams and resident courses. Since its inception, RS JPO has been tasked as the equipment support activity manager for supporting the "in theater" and "training center" sustainment operations for UGS for the Army, Navy, Air Force, and Marine Corps. Currently, training is from neither a systems approach nor a MOS organizational construct identified or designated to perform the training function.

In 2004, the RS JPO established the JRRF in response to urgent operational needs and in support of the joint forces engaged in the theatre of operations for all Joint Service NSE robotic systems. The JRRF's support areas include in-theater sustainment support and individual and unit operations training of robotic systems. RS JPO conducts operator certification courses on all robotic systems currently fielded and intended for users in the theater of operations. Training is currently conducted at Fort Leonard Wood, Missouri; Selfridge Air National Guard Base (SANGB), Michigan; and unit home stations through mobile training teams.

The small robot certification course is a two-day course that provides the operator system uses, characteristics, capabilities, limitations, component identification, pre-mission mechanical and functions checks, and hands-on practical application. Personnel are required to successfully complete a practical exercise performance evaluation to obtain certification. The M160 operator course is six days long and currently conducted at Fort Leonard Wood.

All robot technicians are trained on tasks that are required for the repair and maintenance of robotic systems supported by RS JPO. This training is achieved via a 10-week robot maintenance and repair course currently taught at SANGB. The course totals 400 hours of training in which the technicians are certified to work on RS JPO-supported robotic systems. Technicians receive operator training and hands-on training in troubleshooting; removing and replacing line replaceable units on currently deployed robotic systems; and using maintainer tools, special tools, and test equipment to maintain robotic platforms.

3985 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Due to increasing robotic sustainment and training demands, RS JPO opened the Robotic University at Fort Leonard Wood on 4 April 2012. This detachment consists of technician bays and classrooms, warehouse space, and office space. Robotic University is truly a one-stop-shop with the ability to repair, supply, and train robotic systems. The Robotics University and SANGB training sites, with their equipment, materials, technicians, and instructors, give service members the required skills and confidence in the robotics.

7.4.3 Unmanned Maritime Systems

The Navy currently has a number of UMS consisting of USVs and UUVs that perform a variety of missions including mine warfare, mine neutralization, reconnaissance, surveillance, hydrographic surveying, environmental analysis, special operations, and oceanographic research. These systems vary in size and displacement and run from man-portable systems to systems 40 feet in length and several thousand pounds in displacement. These systems are predominately launched from submarines or surface ships and recovered and maintained aboard those vessels. The new Littoral Combat Ship (LCS) employs the largest inventory of unmanned systems for a variety of missions including surface warfare (SUW), anti-submarine warfare (ASW), and mine countermeasures (MCM).

UMS training consists of an assortment of methodologies that provide an optimal learning environment and include classroom as well as hands-on training. Classroom instruction consists of the fundamentals of operation and maintenance while the hands-on training covers the practical application of that knowledge. Follow-on and refresher training is provided by computer-based training (CBT) that includes online simulations of actual operations. Training is conducted at the appropriate training center, such as the Mine Warfare Training Center in San Diego, California, or at the Warfare Center that is the core support center for the specific system.

LCS Detachments consisting of up to 15 officers and technicians are assigned to LCS for each of the respective Mission Modules (i.e., SUW, ASW, MCM) and undergo classroom and hands-on training before boarding LCS for a deployment. As the personnel rotate on and off one LCS to other assignments and then back again, refresher training is provided at the Shore Based Trainer in San Diego. It includes individual CBT consoles and team training consoles to help sharpen previously learned skills. There are also CBT modules that can be downloaded for continuous training while aboard the LCS. Additional training centers will be established in Fort Lauderdale, Florida, and at various overseas locations as warranted to maintain detachment proficiency.

7.4.4 The Acquisition Process

Much has already been said in this document about the challenges created by the rapid acquisition of unmanned systems in response to urgent operational needs. As the immediacy of urgent operational needs begins to slow, the unmanned systems acquisition process will begin to normalize. As requirements for new generations of unmanned systems are generated, training must be developed concurrently with the new systems. Associated costs should be appropriately addressed across the program life cycle. The training KPP is required to eliminate ad hoc training systems at delivery.

3986 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

7.4.5 The Regulatory Environment

The regulatory environment is a unique challenge to unmanned systems operations, particularly in peacetime. While all systems are governed by regulatory requirements of one sort or another, unmanned systems bring with them an additional set of procedural and safety concerns because they are *unmanned*. These concerns are further increased with discussions of system autonomy. Much attention is being given to UAS autonomy, but it is not unique to UAS. How to train with an unmanned truck, for example, designed to move along roadways in a combat environment presents challenges when trying to traverse the U.S. interstate system and local county roads. Regulatory oversight may have the most significant impact on basing decisions and training operations, especially for UAS.

7.4.6 Technology

Technology challenges for training can be grouped into two categories: 1) the need to train to new missions and affiliated technologies and 2) technology impacts on training. New missions, hardware developments, and software integration appear to be endless. Each has to be accompanied by associated training. For example, access to airspace may be enhanced by SAA technologies that open up more opportunities for live training. Conversely, high-fidelity simulators and the availability of surrogate platforms could lessen the dependence on live training. Some technology impacts may not be so direct, but may be important none the less. For instance, a common control system not only has a training component, but could also lessen manpower requirements by leveraging the ability of a single operator to control multiple systems simultaneously. As a result, training throughput requirements and manpower resources could be decreased.

7.4.7 Manpower

Training faces several manpower challenges. First is the need for a sufficient instructor cadre. With ongoing contingency operations, qualified and potential instructors are often unavailable. Second, the Services have to address personnel qualifications and requirements, to adjust force structure, and to revise personnel processes to accommodate the new technologies. These actions affect the training audience. The coordination and integration of operators, force structure, and data analysts impact how training is accomplished and how training affects human resources. Manpower considerations for training must be fully explored to attain mission efficiencies and readiness.

7.4.8 Asset Availability

Adequate training resources are another challenge. First, similar to unavailability of instructors because of real-world operations, actual unmanned system platforms are often not available for training. This lack of platforms can be mitigated by leveraging the use of simulation and surrogates. Second, programs need training capability assets, such as realistic target sets in representative terrain, runways, scoring and feedback systems for crewmember after action reviews, access to airspace and frequency spectrum, simulators and surrogates, communications infrastructure, and C2 organizations and processes at ranges. Low-cost training munitions that replicate the service munitions of weaponized platforms will also need to be developed to facilitate realistic training within budgetary constraints and installation range limitations. These

3987 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

assets can be integrated into training requirements and plans. Moreover, the assets can influence basing decisions, operations, and funding strategies.

7.4.9 Policy and Documentation

Processes for capturing lessons learned and developing Service and joint doctrine and TTPs must be established and institutionalized through policy and documentation. Policy and documentation serve as the basis from which the Services develop training CONOPS, requirements, and plans. DoD, Service, and Joint plans identify and describe how the populations will be exposed to unmanned systems through professional military education and training. Training strategies for weaponized unmanned systems must identify the types and quantities of munitions required to maintain operator, crew, or unit proficiency in a training environment. Additionally, policy, documentation, and plans codify career paths and expectations for unmanned systems leaders, operators, planners, maintainers, and users.

7.5 The Way Ahead

Despite the challenges introduced by the rapid acquisition and fielding of unmanned systems, these systems are providing valuable capabilities to CCDRs today. Introduction of new systems and processes are traditionally fraught with growing pains, including in training. It is through their perseverance, ingenuity, and professionalism that our soldiers, sailors, airmen, and marines can adjust to ever-changing circumstances to maintain mission readiness and combat effectiveness. As DoD moves toward an environment where unmanned systems needs are more mature and the acquisition process normalizes, training processes and systems will also mature. While the real-world environment flexes with real-world contingencies and the realities of domestic unmanned systems training become more imminent, DoD is addressing training challenges as follows:

- The requirement and acquisition processes will continue to be reviewed for inclusion of training plans throughout a program's development to help improve the rapid acquisition process. Current policy requires a draft training plan at each acquisition milestone. Additionally, new policy is being developed to strengthen those requirements and provide guidance for developing training for rapid acquisition programs. The policy will also offer a training plan template for the Services to support an appropriate training strategy.
- Organizations within DoD are working with regulators, other government organizations, and industry on how to safely incorporate these new technologies into today's world on an ongoing basis. For example, the Airspace Integration IPT and UAS ExCom, discussed in Chapter 5, will continue to implement products and activities to incrementally gain access to the NAS with the goal of attaining the level of UAS access to the NAS necessary to complete training and readiness requirements.
- Training plans will be developed and updated to reflect modifications to legacy systems and introduction of new systems. DoD will continue to develop SAA technologies to gain access to the NAS, increase commonality across control systems, increase autonomy of systems, and align fidelity of simulators for appropriate phases of training. Additionally, long-term success can be economically achieved with increased commonality of hardware to reduce unnecessary unique systems training.

3988 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

- As forces redeploy, the availability of instructors to fill training positions at all levels is expected to increase. As initial manning quotas are met, cross-flow accessions will be curtailed, and schoolhouses will transition to steady-state throughputs. As newly established career fields grow, season, and develop, experience levels will increase and normalize, similar to other career fields across the forces. Personnel systems will continue to align to the new technologies and mature.
- As forces return to home station from the current operational contingencies, decisions will be made about which systems become enduring PORs and transition back with the forces. It is envisioned that the redeployment will increase the availability of assets for training. Service and Joint training plans will need to mature and add the specificity needed to make prudent basing and resourcing decisions that enable effective training.
- Service roadmaps will continue to evolve and mature along with the doctrine, training plans, and documentation needed to support robust training systems. Emphasis will be put on fostering jointness and incorporating cross-service participation during exercises. A comprehensive training strategy will be developed to guide the myriad of efforts across DoD and help ensure effective and efficient training. The strategy will leverage work already completed or underway within the Services and Joint Staff. Its scope will be broad to address the totality of UAS training, from the smallest to the largest systems, at all echelons, for all appropriate personnel, and across the training continuum.

A notional timeline for UAS training objectives is presented in Figure 39 and will be further refined upon completion of the UAS training strategy in FY2013. By overcoming these training challenges and developing a DoD-wide training strategy, future unmanned systems will deliver more effective warfighting capabilities to the battlefields of tomorrow.

3989 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

8 International Cooperation

8.1 Introduction

DoD international cooperation efforts include the cooperative research, development, test, and evaluation of defense technologies and systems with foreign partners as well as the procurement of defense articles, systems, and services from foreign partners. It also includes participation in NATO capability groups. The objectives of international cooperation are

- ***Operational.*** To increase military effectiveness through interoperability and partnership with allies and coalition partners.
- ***Economic.*** To reduce weapons acquisition cost and achieve better buying power by sharing costs and economies of scale, avoiding duplication of development efforts, and cooperatively producing or selling more weapons systems to our allies and friends.
- ***Technical.*** To access the best defense technology worldwide and minimize the capabilities gap with allies and coalition partners.
- ***Political.*** To strengthen alliances and relationships with other friendly countries.
- ***Industrial.*** To bolster domestic and allied defense industrial bases.

8.2 Methods of International Cooperation

Three primary methods are used for international cooperation:

- International agreements such as memoranda of agreement/understanding (MOAs/MOUs) aimed at joint research, development, and/or procurement of, or investment in, new defense technologies and systems
- Foreign military sales (FMS)
- Direct commercial sales (DCS)

8.2.1 MOAs and MOUs

DoD has entered into bilateral and multilateral agreements with a variety of international partners for the joint development of defense technologies and systems. Under such agreements, DoD works with its foreign counterparts and shares existing technology, expertise, and resources to develop new technical information; develop new technology, defense systems, or platforms; or improve existing products. DoD has entered into several such international cooperative agreements with foreign partners to advance UAS. For example, The Technical Cooperation Program (TTCP), a collaborative defense S&T program involving the United States, Great Britain, Canada, Australia, and New Zealand, was established to familiarize all partners with each other's national defense S&T programs and to cooperate in a broad range of defense S&T activities and projects. The results of TTCP activities assist each participant in meeting defense requirements, while avoiding unnecessary duplication of effort. The participants of TTCP have an active UAS program to share and conduct joint experiments in areas such as autonomous C2, novel aircraft configurations and systems, UAS self-protection, and counter-UAS. This activity has spawned an International Operators' Group, which includes both operators and researchers to identify and address pervasive issues, as well as a number of bilateral agreements with individual nations.

3990 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

8.2.2 Foreign Military Sales (FMS)

The FMS program is the U.S. Government's program for transferring defense articles, services, and training to other sovereign nations and international organizations. Under FMS, DoD procures defense articles and services on behalf of the foreign customer using the same acquisition process DoD uses for its own military needs. Countries approved to participate in this program may obtain defense articles, services, or training by paying with their own national funds or with funds provided through U.S. Government-sponsored assistance programs. In certain cases, defense articles, services, and training may be obtained on a grant basis. The Defense Security Cooperation Agency administers the FMS program for DoD. FMS cases must be reviewed/approved through the Department of State (DoS), and, in some cases, the U.S. Congress must be notified through the Congressional Notification process. In general, these government-to-government purchase agreements tend to ensure standardization with U.S. forces, provide contract administration services that may not be available through the private sector, and help lower unit costs by consolidating purchases for FMS customers with purchases for DoD.

8.2.3 Direct Commercial Sales (DCS)

Under DCS, U.S. companies obtain commercial export licenses from either DoS (for munition items) or the Department of Commerce (DoC) (for dual-use items). These licenses allow the companies to negotiate sales directly with foreign customers. All DCS are subject to the approval of DoS or DoC and, in some cases, the U.S. Congress and must comply with applicable U.S. exports laws and regulations. DCS allows the foreign customer more direct involvement during contract negotiation, may allow firm-fixed pricing, and may be better suited to fulfilling nonstandard requirements.

8.2.4 NATO

The military alliance promotes cooperation and interoperability through information exchange and the development of standards (see http://nsa.nato.int/nsa). For example, airworthiness standards have been developed and adopted by member nations and are being incorporated in MIL-HDBK-516B.[87] Additionally, the alliance is acquiring (under DCS) the NATO Alliance Ground Surveillance (AGS) System, a derivative of the U.S. Global Hawk system. Five Europe-based AGS aircraft will serve alliance missions and, in turn, reduce demand for U.S. ISR systems to meet NATO requirements. See Appendices B and C of this roadmap for additional information on alliance standards, and see the publication AAP-03[88] for established procedures for the production, maintenance, and management of NATO standardization documents in accordance with NATO regulations.

8.3 International Cooperation Authority, Jurisdiction, Approval, and Disclosure

The U.S. Government has split export licensing authority for FMS and DCS among multiple organizations. The two primary Government regulations are the International Traffic in

[87] MIL-HDBK-516B, Airworthiness Certification Criteria.
[88] AAP-03, Production, Maintenance and Management of NATO Standardization Documents, Edition J, Version 2, November 2011 (http://nsa.nato.int/nsa).

3991 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Arms Regulation (ITAR), which controls defense articles and services under the jurisdiction of DoS, and the Export Administration Regulation (EAR), which controls dual-use items under the jurisdiction of DoC.

8.3.1 Authority and Jurisdiction

8.3.1.1 International Traffic in Arms Regulation (ITAR)

The Arms Export Control Act (22 U.S.C. 2778) authorizes the President to control the export and import of defense articles and services. Pursuant to Executive Order 11958, this statutory authority was delegated to the DoS. ITAR implements that authority and is the governing regulation controlling the export of defense articles and services. ITAR includes the U.S. Munitions List, a list of defense articles controlled by ITAR. It further defines the export licensing requirements and procedures needed to export a defense article or perform a defense service as well as the process to determine the jurisdiction of a commodity (i.e., whether an item is controlled under ITAR or EAR).

ITAR provides a number of exemptions to the licensing requirements for defense articles and services. Many of these exemptions are country specific (e.g., through implementation of UK and Australian defense trade treaties, the Canadian exemption) while others are transaction specific (e.g., shipments by or for U.S. Government agencies). Most ITAR exemptions have rigorous procedures, documentation, and record-keeping requirements associated with their implementation. Each of the U.S. military services, as well as other select DoD organizations, has been delegated limited export authority by the DoS.

8.3.1.2 Export Administration Regulation (EAR)

EAR implements the Export Administration Act (EAA) of 1979. DoC has statutory authority for implementing EAA, which governs the export of the dual-use items identified in EAR's Commodity Control List (CCL). "Dual use" refers to EAR-controlled items that can be used both in military and other strategic uses and in civil applications and are distinguished from items with weapon and military-related use or design that are subject to DoS control or the Department of Energy's nuclear-related controls. EAR delineates license requirements for dual-use controls and, similar to the ITAR, provides for licensing exemptions. Note that not all items on the CCL require a license for release to all countries, and some commodities not specifically listed on the CCL could require an export license for select end uses and end users.

8.3.1.3 Foreign Disclosure

Decisions to disclose classified military information are often tied to security assistance and arms cooperation programs or to the transfer of defense articles; therefore, the National Disclosure Policy (NDP-1) must be in compliance with the provisions of the Arms Export Control Act and the Conventional Arms Transfer Policy. The release of classified military information for all U.S. Government disclosure activities must support U.S. foreign policy and military objectives. The basis for the release or denial of classified military information is twofold: a judgment by designated disclosure authorities that 1) the foreign recipient has the capacity and intent to provide adequate security protection to the information and 2) the national interest (foreign policy or military) will benefit.

3992 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The policy provides for operation by exception. Exceptions to the policy may be decided by the Secretaries of State and Defense, their principal deputies, or the National Disclosure Policy Committee (NDPC). In most instances, the NDPC grants exceptions to policy. After deliberation by the NDPC, disclosure authority is delegated to the heads of departments and agencies responsible for the information within certain security classification limits (e.g., top secret, secret, or confidential) for specified categories of classified military information. Considered in establishing these limits for each country or international organization are the following factors:

- Evaluation of the capability to protect the information based on a favorable NDPC security survey and/or a Central Intelligence Agency assessment of the risk to the information
- Existence of a formal government-to-government security agreement providing for the protection of the information
- Existence of a mutual defense or similar arrangement
- Frequency of disclosure

8.3.2 Approval and Disclosure

8.3.2.1 Technology Security

DoD has created 12 technology security review processes. Each process has responsibility for select technologies. For example, these processes include low-observable and counter-low-observable technology, GEOINT, communications security (COMSEC) devices, intelligence data, GPS, data links and waveforms, and night vision devices. Prior to the export (or implied export) of any item or technology controlled by the various technology security processes, the responsible process must be engaged and provide its concurrence with the proposed transfer.

8.3.2.2 Conventional Arms Transfer (CAT) Policy

The CAT policy is the standing Presidential policy guidance on arms transfers.[89] It is intended to promote restraint in the transfer of U.S. weapons systems, while supporting U.S. national security and foreign policy objectives and meeting the legitimate defense requirements of allied and friendly nations. DoS is responsible for articulating this policy and plays a major role in any proposed changes to it. DoS action officers use the CAT policy in case-by-case reviews of proposed transfers to determine whether a particular transfer of military equipment and/or services meets the 12 criteria established by the policy. This list of criteria can be found at http://www.state.gov/t/pm/rsat/c14023.htm.

8.3.2.3 Congressional Notifications

Pursuant to Section 36(b) of the Arms Export Control Act, the Executive Branch is required to formally notify the Senate Foreign Relations Committee and the House Foreign Affairs Committee when a potential FMS meets or exceeds specified dollar thresholds. Bureau of Political-Military Affairs Office of Regional Security and Arms Transfer (PM/RSAT) officers

[89] Presidential Decision Directive 34 (PDD-34), Conventional Arms Transfer Policy, 17 February 1995.

3993 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

work with Bureau leadership and DoD to make the required notifications, including briefing Congressional staff on the potential arms sale and how it will serve U.S. interests.

8.4 Special UAS-Related Considerations

In addition to the above general constraints, certain considerations are unique to UAS, i.e., they normally do not apply to other unmanned systems.

8.4.1 Missile Technology Control Regime (MTCR)

MTCR is an informal and voluntary association of countries that share the goals of nonproliferation of unmanned delivery systems capable of delivering WMDs and that seek to coordinate national export licensing efforts aimed at preventing WMD proliferation. MTCR rests on adherence to common export policy guidelines that are applied to an integral common list of controlled items. The greatest restraint (i.e., "a strong presumption of denial") is applied to what are known as "Category I items." These items include UAS with capabilities exceeding a 300 km/500 kg range/payload threshold, the production facilities for such systems, and any major subsystems.

8.4.2 Armed UAS

DoD and DoS both place a high level of scrutiny on the export of armed UAS. In addition, the U.S. Congress has previously expressed reservations over the release of armed UAS to any but our closest allies.

8.5 Reform Efforts

The U.S. Government and DoD have initiated a wide variety of reform efforts that will affect the DoD processes and procedures involved in international cooperation. Although not an exhaustive list, 8.5.1 through 8.5.4 highlight some of the current major reform efforts that will likely affect international cooperation related to unmanned systems.

8.5.1 Security Cooperation Reform

The FY12–16 Defense Planning and Programming Guidance[90] called for establishing a task force to conduct a comprehensive review of DoD's security cooperation processes. Specific requirements included the development of options for adjusting the operational direction, control, and authority of agencies implementing security assistance; options for aligning and streamlining security assistance and technology transfer processes, organizations, and regulations; a plan to implement a certification curriculum for security cooperation professionals similar to that for the defense acquisition workforce; and a plan to consider authorities, alignment of planning and resources, organizational change, and key processes. After analysis and outreach, the Security Cooperation Reform Task Force (SCRTF) revealed a series of findings and took a two-pronged approach to build an "anticipatory" system with a "fast-track" capability for urgent partner needs.

[90] FY12–16 Defense Planning and Programming Guidance, para. 6.3, Reform Security Cooperation (U), pg. 30, 20 May 2010.

3994 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

SCRTF identified a set of 58 recommendations across five focus areas: planning, FMS process (i.e., contracting, procurement, transportation, and distribution) improvement, accelerated delivery, workforce development (training and education), and technology security and foreign disclosure.

In July 2011, SECDEF directed that the SCRTF recommendations be implemented and that SCRTF — under the direction of the Chairman of the Joint Chiefs of Staff and the USD(Policy) — oversee implementation of the recommendations in the report.

8.5.2 Defense Exportability Features (DEF)

The DEF program is intended to ensure that the design and engineering of export variants of U.S. systems are initiated early in the acquisition process to increase the security of sensitive U.S. technology, avoid the high cost of developing an export variant from a fully engineered and implemented U.S. system, and achieve better buying power through the economies of scales realized through increased international procurement. The DEF pilot program was authorized in the FY2011 National Defense Authorization Act. In FY2012, four programs, including a Navy UAS, conducted DEF feasibility studies. These assessments identify the potential benefits and costs of providing protection to critical program information for the export variants in the design.

8.5.3 Export Control Reform (ECR) Initiative

In August 2009, the President directed a broad-based interagency review of the U.S. export control system, with the goal of strengthening national security and the competitiveness of key U.S. manufacturing and technology sectors by focusing on current threats and adapting to the changing economic and technological landscape. This review determined that the current export control system is overly complicated, contains too many redundancies, and, in trying to protect too much, diminishes our ability to focus our efforts on the most critical national security priorities. The Administration has determined that fundamental reform of the current system is necessary to overcome the inefficiencies and redundancies of a set of systems within a system.

As a result, the Administration launched the ECR Initiative, which is a common sense approach to overhauling the nation’s export control system. The ECR Initiative, which is not related to the President’s National Export Initiative, is designed to enhance U.S. national security and strengthen the ability of the United States to counter threats such as the proliferation of WMDs. The purpose of export controls is to ensure that items do not end up in the hands of someone who intends to harm the United States or its allies. It is a risk-based system, where items are generally authorized for export to low-risk destinations, while other items may be allowed to other destinations after closer scrutiny and some items may be denied.

The Administration is implementing the reform in three phases. Phases I and II reconcile various definitions, regulations, and policies for export controls, while building toward Phase III, which will create a single control list, single licensing agency, unified IT system, and enforcement coordination center. This implementation plan is designed to resolve core problems first, before focusing on Government reorganization. The consolidation plan in the final phase would eliminate the need to keep the systems within a system fully synchronized, by eliminating these separate systems. This common sense approach is good government, especially in this era of tightening budgets.

3995 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

8.5.4 Technology Security and Foreign Disclosure (TS&FD)

The Export Control Reform Task Force Report (issued 29 January 2010) recommended the initiation of an effort "to streamline and harmonize" U.S. Government TS&FD processes. As a result, the Deputy Secretary of Defense tasked USD(AT&L) and USD(Policy) to conduct a review of DoD-led TS&FD processes and provide alternative TS&FD system concepts to enhance transparency, predictability, and timeliness while maintaining the overall high quality of U.S. Government decision making in this key area.

The U.S. Government currently has 13 separate, internal TS&FD processes in which DoD either leads or is a key participant. These processes are generally reactive in nature and do not anticipate building partner nation capacity requirements. Since these processes are neither integrated nor harmonized with each other, the lack of transparency and predictability in the U.S. Government TS&FD decision-making processes makes it difficult to synchronize U.S. Government activities to build partner nation capacity, which includes Washington arena, country team, CCDR, partner nation, and U.S. and foreign industry involvement.

DoD's current TS&FD activities are focused on three areas:

- Establishing a TS&FD office to serve as the central processing organization of DoD decisions that affect DoD aspects of TS&FD release requests.
- Developing and issuing revised DoD and U.S. Government policy guidance to consolidate and restructure current U.S. Government TS&FD decision-making processes to enhance the quality, timeliness, and efficiency of DoD's overall TS&FD decision making.
- Implementing overarching improvements in DoD for building partner nation capacity, defense exportability features, industry and partner outreach, and DoD workforce initiatives oriented toward proactive — rather that purely reactive — TS&FD decision making.

9 Summary

While DoD unmanned systems development funding may taper off over the early part of this decade, unmanned capabilities hold much promise for domestic commercial applications and personal consumer use. This trend could indeed reduce the price point of these systems for the military, which is good news for the U.S. taxpayer. However, if the technical challenges to unmanned systems development and operations are addressed by accomplishing the technical projects and tasks described in this roadmap, advances in capability can be readily achieved by the Services well beyond what is achievable today. See Figure 40.

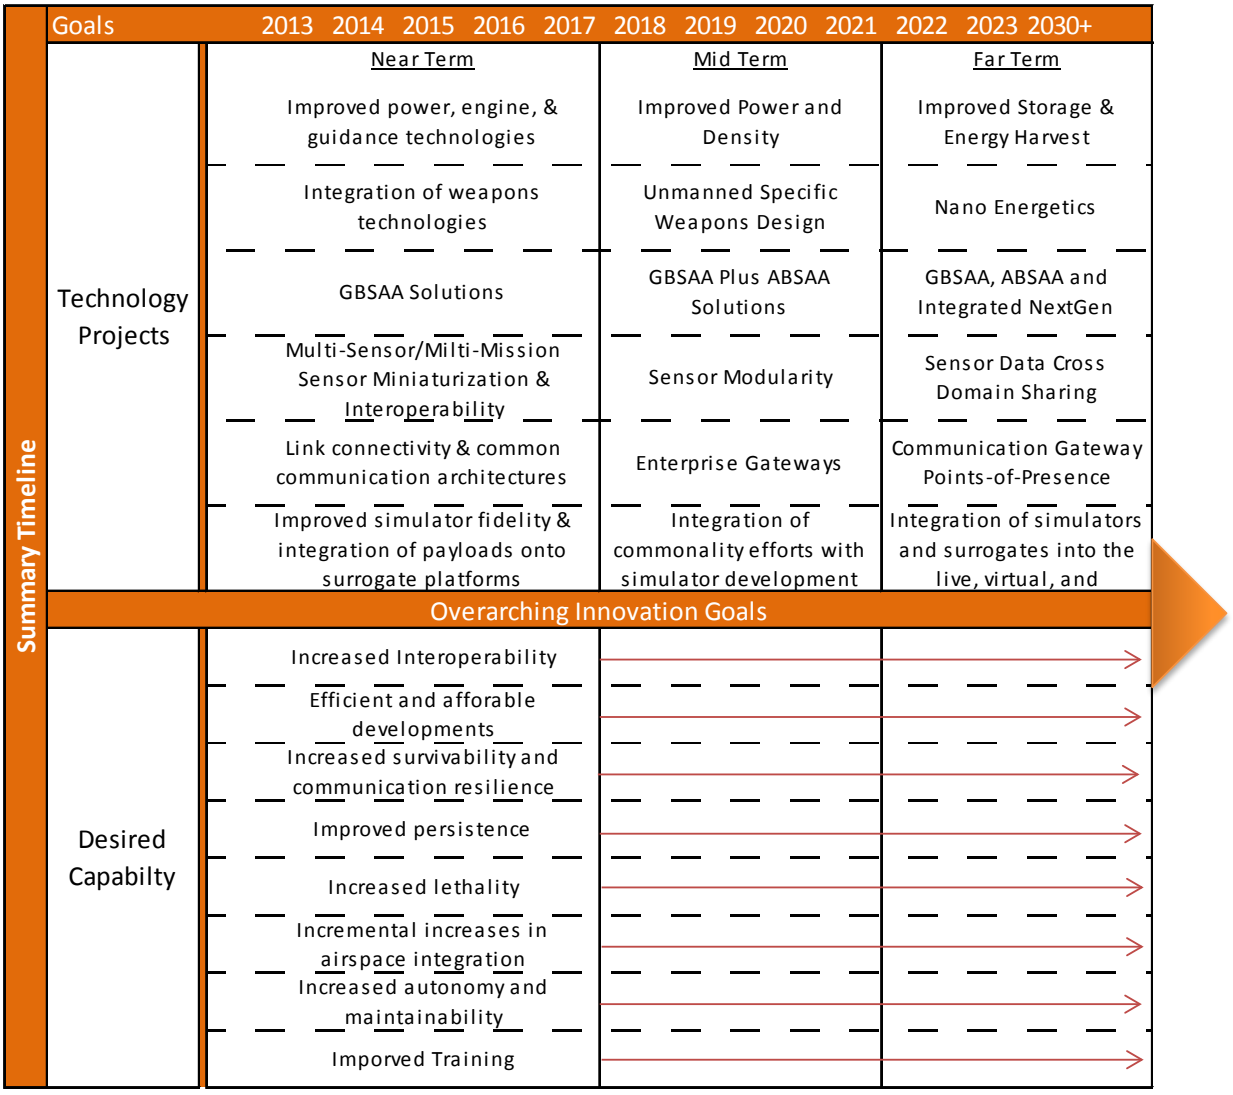

Figure 40. Overarching Innovation Goals Timeline

As the unmanned industry moves toward more deliberate and traditional program developments, it is imperative these future capabilities be addressed by the Service requirements managers as new programs are initiated. Working together with industry, academia, and other agencies, DoD will continue to map an affordable path using emerging technologies as a basis for future warfighter capabilities.

Appendix B PRIORITY INTEROPERABILITY STANDARDS

The list of standards below is not all-inclusive; rather the list focuses on priority standards for joint interoperability and UI2 CBA gaps. To be effective, policy and standards require DAE and SAE commitment, oversight, and enforcement prior to approving applicable JCIDS milestones (and DoD architecture framework products), Interoperability Certification and Information Support Plans (ISP). These priorities will be updated during biannual reviews of this Roadmap (or sooner by exception).

- **USIP 1.1 Line of Sight Transmission of Motion Imagery for Battlespace Awareness Using Standard Common Data Link.** Mandated standard available on DISR, 30 November 2010. Interoperability Profiles (IOPs):

  IP 1.1: Motion Imagery for Situational Awareness Governing Standards. These standards are the basis for the implementation and take precedence.
  - ✓ MISP 5.1, Motion Imagery Standards Profile, December 2008
  - ✓ Motion Imagery Standards Board (MISB) Standard 0601.2 UAS Datalink Local Metadata Set, October 2008
  - ✓ MISB EG 0902, MISB Minimum Metadata Set, May 2009
  - ✓ IETF RFC 0768, User Datagram Protocol, August 1980
  - ✓ IETF RFC 0791, Internet Protocol (IPv4), September 1981

  Other Applicable Standards. These references are cited by the governing standards and provide further specification detail to completely define the implementation.

  - ✓ MISB Standard 0807, DoD/I/NSG Motion Imagery Metadata Registry
  - ✓ MISB Standard 0604, Time Stamping Compressed Motion Imagery
  - ✓ MISB Standard 0102.5, Security Metadata Universal and Local Data Sets for Digital Motion Imagery
  - ✓ MISB RP 0603, Common Time Reference for Digital Motion Imagery Using Coordinated Universal Time
  - ✓ MISP RP 0903, Video Moving Target Indicator Local Data Set
  - ✓ ISO/IEC 13818-1:2007, Information Technology — Generic Coding of Moving Pictures and Associated Audio Information: Systems
  - ✓ SMPTE 335M-2001, Metadata Dictionary Structure
  - ✓ SMPTE 336M-2007, Data Encoding Protocol Using Key-Length Value
  - ✓ SMPTE RP210.10-2007, Metadata Dictionary Registry of Metadata Element Descriptions
  - ✓ NGA.STND.0024-2_1.0, Sensor Independent Complex Data (SICD) for complex SAR imagery
  - ✓ NATO STANAG 4676, NATO Intelligence, Surveillance, Reconnaissance Tracking Standard (NITS)—Key enabler for UAS information fusion, currently used to “make sense” of GMTI “dots”
  - ✓ NATO STANAG 4607, Ground Moving Target Indication Format (GMTIF)
  - ✓ NATO STANAG 4559, NATO Standard Image Library Interface (NSILI)—currently edition 3, the next edition will be XML capable—used to share and expose data between systems

4000 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

- ✓ NATO STANAG 3277, Joint ISR Task and Request Data Format—cross-cue and sensor task request implementation
- ✓ Theater Net-centric Geo-location (TNG) Joint Interface Control Document (JICD)—SIGINT interoperability
- ✓ JPEG 2000, Interactive Protocol (JPIP)—useful in large format sensor applications like wide area surveillance sensors
- ✓ SMPTE 296M-2001, 1280 x 720 Progressive Image Sample Structure — Analogue and Digital Representation and Analogue Interface
- ✓ SMPTE 274M-2008, 1920 x 1080 Image Sample Structure, Digital Representation and Digital Timing Reference Sequences for Multiple Picture Rates
- ✓ SMPTE 295M-1997, 1920 x 1080 50-Hz — Scanning and Interface
- ✓ NATO STANAG 4609, AIR (Edition 2) — NATO Digital Motion Imagery Standard
- ✓ AEDP-8 (Edition 2), NATO Motion Imagery (MI) STANAG 4609 (Edition 2) Implementation Guide
- ✓ MIL-STD-2500C, National Imagery Transmission Format (NITF) Version 2.1 for the National Imagery Transmission Format Standard

IP 2.1: Managed Configuration of STD-CDL Terminals Governing Standards:

- ✓ Specification Number 7681990, Rev H, Performance Specification for the Standard Common Data Link Waveform
- ✓ Specification Number 60038365, Capstone Specification for the Network -Centric Common Data Links
- ✓ NATO STANAG 7085, Interoperable Data Links for Intelligence, Surveillance, and Reconnaissance (ISR) Systems, Edition 3, pending promulgation https://gtg.csd.disa.mil/uam/marketing.jsp

Appendix C DOD INITIATIVES TO INCREASE INTEROPERABILITY AND MODULARITY

UI2 CBA

This CBA is the culmination of a joint WG effort to conduct an operational assessment of unmanned systems interoperability task needs, identify and prioritize gaps in the ability to satisfy these needs, and identify potential DOTMLPF-P priorities to mitigate the identified capability gaps. Each military department and agency will find aspects of the CBA relevant to its mission responsibilities. The I-IPT under the UAS Task Force will continue to work with the military departments and agencies to close gaps identified within the CBA to ultimately improve capability to the warfighter.

The CBA effort derived the 29 prioritized joint UAS interoperability gaps, which are listed below. The complete approved CBA is available on the USD(AT&L) restricted Unmanned Warfare Information Repository website.

- Detect or sense and avoid other airspace users in accordance with NAS standards and tactical requirements for deconfliction and collision avoidance.
- Provide selectable ISR data in joint approved network formats and waveforms.
- Provide ISR, tracking data, and location information in common, discoverable, retrievable, selectable formats to authorized subscribers across domains, including C2 interfaces such as Blue Force Tracker.
- Provide accurate position reporting sufficient for joint common operational picture and joint common air picture applications.
- Provide location information from all sensors for ISR contacts of interest from UAS to authorized subscribers, including the transfer of targets in different domains, e.g., for the transfer of a subsurface maritime contact by a UA. (Authorized subscribers include direct machine-to-machine data exchange.)
- Provide accurate UA position reporting sufficient for safe and effective operation in NAS airspace and theater airspace.
- Enable vehicle/payload control by all authorized joint users with approved control mechanisms.
- Provide UAS sensor point and area of interest location information to authorized subscribers in the specified format.
- Enable multiple authorized controllers (subscribers/requests) to control and transfer control of the vehicle (and/or payloads) and to accept transfer of control between approved control nodes (including when payloads are able to support multiple users simultaneously) (will require the capability to assess and prioritize requests).
- Provide communication gateway and aerial network or network node services compatible with appropriate joint networks.
- For appropriately equipped UAS, provide target designation in accordance with requirements of precision joint munitions (such as JAGM, Hellfire, and small diameter bomb).
- Provide and/or exchange payload and mission information to authorized subscribers in the specified format.

4003 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

- Transmit, relay, or retransmit required voice transmissions or sensor data in accordance with joint standards to authorized DoD and non-DoD subscribers.
- Provide fire support functions that are compatible with joint targeting control systems and procedures.
- For both manned and unmanned platforms, provide airborne handoff of missions or services between platforms.
- Enable authorized users to access data archive and retrieval systems.
- Integrate with the unmanned systems environment to C2 sensor fields using other unmanned sensors and platforms.
- Provide and enable joint information operations and information warfare effects including electronic attack, electronic protection, and EW support that is compatible with joint EW attack systems and appropriate requirements for "hardening" against EW threats.
- Deliver lethal or nonlethal effects in accordance with joint TTPs.
- Provide battle damage assessment input data in joint approved formats to authorized subscribers and assessment teams.
- Provide meteorological and oceanographic data in common, discoverable, retrievable format to authorized subscribers.
- Provide chemical, biological, radiological, nuclear, and high-yield explosive data in prescribed format to authorized subscribers.
- Simultaneously control multiple air vehicles of either similar or dissimilar types from a single control station.
- Provide multiple authorized users (GCS or manned aircraft) with the capability to control target designation and weapon launch in accordance with joint TTP.
- Provide nonmilitary data compatible with federal and state agencies in support of a range of disaster, wildfire, and rescue operations.
- Provide platform-operating status by UAS class sufficient to facilitate transfer of control (handover) of the air vehicle or systems within the joint force to facilitate safe operation.
- Provide platform health indicator information to authorized controllers in the specified format.
- Perform launch and recovery under the control of multiple authorized and capable joint users and facilities (terminal phase of operations).
- In situations involving a loss of control link or loss of communications, comply with DoD contingency procedures.

Standards and Governance Efforts

DoD can accomplish unmanned systems interoperability by standardizing critical interfaces within the overall UAS architecture and implementing standard IOPs. DoD must clearly and consistently define the communication protocols, message formats, and implementation methods across these interfaces. The I-IPT will work with DoD partners, the Services, and the Joint Staff to define and enforce the standard IOPs through the USIP WG and the UCS WG for incorporation into the JCIDS processes. This effort will facilitate the mandated acquisition, technology, and logistics lifecycle management efficiencies across current and future UAS programs.

4004 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The OSD defines OA as follows:[91]

A multifaceted strategy providing a framework for developing joint interoperable systems that adapt and exploit open-system design principles and architectures. This framework includes a set of principles, processes, and best practices that:

- ✓ Provide more opportunities for competition and innovation
- ✓ Rapidly field affordable, interoperable systems
- ✓ Minimize total ownership cost
- ✓ Optimize total system performance
- ✓ Yield systems that are easily developed and upgradeable
- ✓ Achieve component software reuse

UCS OA is the business model foundation on which all USIPs and Service IOPs should be based. In some instances, USIPs and/or Service IOPs may be incorporated into the UCS framework; however, the overarching intent is to ensure synchronization and compatibility among UCS, USIP, and Service IOP directives.

UCS Architecture

The UCS Architecture is a framework representing the software-intensive capabilities of current and emerging UAS programs in the Army, Navy, and Air Force inventories. The goal is to develop an architecture based on SOA principles, which will be adopted by each Service as a common business model for acquiring, integrating, and extending the capabilities of the control systems for UAS. Under direction from the USD(AT&L) Acquisition Decision Memorandum (11 February 2009), the UAS Task Force chartered the UCS WG to develop and demonstrate a common, open, and scalable architecture supporting UAS Groups 2–5. The UCS WG comprises Government and industry representatives and operates collaboratively using a technical society model where all participants are encouraged to contribute in any area of interest. In this context, the UCS Architecture supports the following OSD-stated high-level business objectives:

- Acquisition flexibility for control segment subsystems and components
- Cost control
- Innovation at all levels of industry
- Reduced integration time for new capabilities
- Reuse across Service and joint UAS programs where appropriate

Upon completion of UCS Architecture version 2.1, the UCS WG is planning to transition to the Army's Aviation and Missile Research, Development and Engineering Center (AMRDEC) Joint Technology Center/Systems Integration Lab (JSIL) at Redstone Arsenal for enduring governance, oversight, management, and custodianship of the UCS business model, interfaces, web repository, and future revisions to the UCS Architecture and/or interfaces. JSIL will establish the UCS Steering Committee (SC) and continue to support OSD and the service acquisition portfolio managers. JSIL will stay synced with USIPs, ICWGs, and IOPs and will be the Government lead for both the UCS SC and USIP SC. In this capacity, JSIL will act as an

[91] Terms and Definitions, Defense Acquisition University: https://acc.dau.mil/CommunityBrowser.aspx?id=22108.

4005 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

unbiased third party to routinely advise OSD, the Joint Staff, and Service acquisition executives on all UCS issues.

The restricted website is https://fusion.dynetics.com/project/UCSWG. To request access, visit the I-IPT public website (http://ucsarchitecture.org), and follow the instructions for requesting access to the restricted website.

Unmanned Systems Interoperability Profiles (USIPs)

USIPs are the implementation of the mandate by the Deputy Secretary of Defense's "Unmanned Aircraft System (UAS) Memorandum 14667-07" (13 September 2007) to develop standard IOPs linked to JCIDS documents. They help drive the implementation of approved DoD and/or joint interoperability priorities at the Service level and may even require a new Service IOP or revision to an existing IOP.

USIPs also support the CJCSI interoperability requirement by creating specific points of "capability-based interoperability." The purpose of a USIP is to define profiles of standards sufficient to guarantee interoperability in support of a specific mission capability. A USIP may reference DoD standards, Intelligence Community standards, Service-specific IOPs, and commercial standards to achieve capability-based interoperability. All approved USIP standards can be found on DISR.

The USIP WG is currently run by the JSIL and comprises Government and industry representatives in the same enduring governance, oversight, and management role as the UCS SC. This new USIP SC will form an advisory group that is responsible to the UAS Task Force and serves in an unbiased, coordinating role for all UAS Task Force IPTs involved in USIP development, implementation, and initiation. The USIP SC shall coordinate staffing and approval of proposed USIPs with the UAS Task Force, JROC, and JCA functional capabilities boards as required. The USIP SC will remain engaged with the Service ICWG/IOP processes to ensure synchronization and foster the vertical and horizontal cooperation essential to joint interoperability.

The intent of the USIP development and management process is to leverage existing processes within both the DoD acquisition management system and the JCIDS process to develop more capable and interoperable unmanned systems.

- USIP 1 (LOS FMV), approved, in DISR release 11-1.
- USIP 2 (BLOS FMV), to be submitted for DISR release 12-1.
- USIP 3 (Bandwidth Efficient LOS), on hold pending BE-CDL Rev B outcome.
- USIP 4 (Video Control Interface for Region of Interest Delivery), in progress. This effort relates to wide area sensors.
- USIP 5 (Weaponization), in progress.

The restricted website is https://software.forge.mil/sf/go/proj1887. To request access, visit the I-IPT public website (https://software.forge.mil/sf/projects/usip_universal_systems_interoper), and follow the instructions for requesting access to the restricted website.

4006 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Service Interface Control Working Groups (ICWGs)

The intent of a Service-level ICWG is to ensure that UAS program and product managers, developers, Services, and end users actively participate in the development and implementation of Service-specific interoperability solutions. This collaborative organization (Government-industry partnerships) serves as the standards recommendation body chartered within each Service to promote interoperability across various product lines.

The ICWG is a technical "engineering-level" body focused on identifying interoperability solutions for the respective Service's UAS FoS. These select requirements and implementation strategies are published within a set of IOPs and are for use by developers and implementers of new (and potential) UAS and related capabilities. IOP implementation across UAS products facilitates diverse levels of interoperability and is intended to provide the end user with an increased payload utility, a reduced tactical footprint, and an expanded unmanned aircraft platform availability.

The Services as a whole have made significant progress in establishing these ICWGs for unmanned systems for the end-to-end management of interface control. Each Service's ICWG has an independent process for IOP development and configuration control. To ensure horizontal and vertical integration, each Service's ICWG staff is represented within the other's ICWG consortia unmanned systems, including the I-IPT, UCS WG, and USIP WG. Members from both the UCS SC and USIP SC are also represented. The Army established the ICWG process within PEO Aviation's UAS project office. The Navy recently followed suit and is actively working to establish its program under PEO Unmanned Warfare. The Air Force is in the process of vetting approval for the same for unmanned systems and organizations.

In coordination with the USIP SC and UCS SC, ICWGs are ideal bodies to nominate and/or implement USIPs either as a bottom-up nomination or a top-down implementation directive from OSD/Joint Staff. It is envisioned that applicable Service IOPs may be candidates for DoD/joint implementation through the USIP nomination process. Conversely, USIPs and/or UCS Architecture requirements may drive the development of new Service IOPs or modification of existing IOPs. In either case, the overarching intent is to avoid duplicative or conflicting Service IOPs.

Service IOPs

Historically, unmanned systems have used very deterministic point-to-point interfaces; however, provisions of network-centric warfare require UAS programs to implement common standards in support of an FoS type of architecture. Widely accepted or approved standards are often too broadly defined and inadvertently allow compliance but not necessarily interoperability (e.g., CDL standards and MISB standards). Interface "standards" vary and allow for diverse implementation strategies and interpretations. To be truly interoperable, an FoS requires the Service-level development of IOPs.

IOPs provide implementation guidance, best common practices, and profiles of standards to help ensure interoperable systems within a Service. IOPs are tightly coupled to program offices and industry partners because each sponsoring entity (e.g., program, industry partner) typically signs off on the IOP. Service system integration laboratories test against their IOPs to

4007 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

ensure program compliance. IOPs perform a similar function to USIPs but typically have a broader scope. A single IOP may touch on several interrelated capabilities and their associated standards, profiles, practices, etc. IOPs that have support across multiple Services are good candidates for nomination as new bottom-up USIPs.

IOPs are managed by their respective Services and are developed through a collaborative process of various product offices and private industry partnerships. Within IOPs and related publications, each Service attempts to set and enforce only the standards critical to respective UAS interoperability. This approach provides the level of commonality required for interoperation while minimizing the impact on the native capabilities and design for each platform. IOPs contain interface requirements specific to interoperation capability within the various UAS. Additionally, IOP-related products (such as associated performance specifications, implementation guides, and interface control documents) support IOP implementation strategies, provide clarity of intent, and promote the use of emerging technologies expected for future standardization. In Service-specific cases, IOPs may be posted on DISR depending on the nature and approved enforcement or testing mechanisms.

Joint Interoperability Test Command (JITC)

JITC is an organizational element of the DISA Test & Evaluation Directorate and has DoDI 4630 responsibility for certifying joint and combined interoperability of all DoD IT and NSS. JITC follows the processes outlined in DoDI 4630, the DoD CIO Interim Guidance Memorandum, and the JITC Interoperability Process Guide (10 September 2012) to perform joint interoperability testing and certification. It works closely with the Services, Joint Staff, OSD, and DoD CIO to provide recommendations to the Interoperability Steering Group for waivers, extensions, and ultimately full interoperability certification and compliance status reporting to DAEs and SAEs. OSD and JITC are committed to testing reciprocity agreements with the various joint and Service testing facilities to encourage compliance testing earlier in the acquisition and product development process and to support the USIP SC, UCS SC, and ICWGs.

The restricted website (DKO) is available on the public website: (http://jitc.fhu.disa.mil/index.html).

Joint Technology Center/Systems Integration Laboratory (JSIL)

JSIL supports the assessment of system integration readiness during the product development process, prior to actual flight testing. JSIL provides for distributed hardware-in-the-loop testing of payloads, air vehicles, ground system components, and joint interfaces using MUSE in globally distributed command exercises and experiments. The purpose of JSIL is to provide simulation, integration, and a full range of test support to the joint UAS family.

More recently, JSIL was resourced in a program decision memorandum to support OSD, the UAS Task Force, and I-IPT plan of action and milestones. As the UCS WG and USIP WG transition to an enduring role, JSIL will continue to lead the UCS SC and USIP SC in direct support to OSD's acquisition oversight roles for establishing, maintaining, and reporting USIP/UCS implementation and compliance.

4008 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The restricted website is provides more information. To request access, visit the I-IPT public website (https://software.forge.mil/sf/projects/usip_universal_systems_interoper), and follow the instructions for requesting access to the restricted website.

DoD IT Standards and Profile Registry (DISR)

DISR is an online repository of DoD IT and NSS standards and related information, formerly captured in JTA, version 6.0. DISR replaces JTA. All approved USIPs are submitted to DISR.

In addition to the definition of common capability descriptions, standards, data models, and architectures, DoD, through OSD, continues to promote the development of OA tools and implementations to aid system acquisition and development in embracing the OA concepts. These efforts extend across the technology and unmanned vehicle spectrum, from software development kits, to complete architectures, addressing UGS, UMS, and UAS, across the Services. Examples of such tools include the following ongoing efforts on the ground, in maritime spaces, and in airspaces:

1. The JAUS Tool Set (JTS) is a tool to help developers build JAUS-compliant software components without having to be intimately familiar with the details of JAUS. JTS allows an unmanned systems designer to focus on behavior, rather than on messaging, protocol, and other considerations, by providing a graphical user interface service editor, validator, internal repository, C++ code generation, and Hypertext Markup Language (HTML) document generation.

   The Navy and OSD have supported and promoted the use of JTS and have had success incorporating it into development and acquisition efforts. Use of JTS on programs accrues benefits to a number of stakeholders in the acquisition chain and research and development and T&E communities. These benefits include enabling a fair basis for competition among vendors so that true capabilities are evaluated, reducing vendor lock-in on unmanned systems, and enabling the development of a "service repository" for JAUS capabilities that have been developed and are available for reuse. JTS reduces the threshold for entry into developing JAUS-compliant systems, opens the market to small businesses, and drives competition and innovation focused on core technology. In addition, JTS provides an accepted, common validation capability, which is critical to ensure systems maintain compliance with JAUS.

2. The NATO STANAG 4586[92] Compliance Toolkit (4586CT) is an integrated set of software tools that provides passive, interactive, and automated test capability. Its core function is to verify the structure and content of data link interface (DLI) messages against both NATO STANAG 4586 and "private" messages as defined to support service-, mission-, or platform-specific requirements. This nonintrusive capability is provided either in real time or during post-run analysis. Additionally, 4586CT can be interoperable with other DLI-compatible systems in either manual mode (where an engineer monitors and injects DLI messages into the network) or automated mode (in

[92] NATO STANAG 4586, Standard Interface of the Unmanned Control System (UCS) for NATO UAS Interoperability.

4009 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

which 4586CT interacts directly with other DLI systems according to user-defined scripts and procedures).

These capabilities enable 4586CT to perform compliance testing of unmanned systems relative to NATO STANAG 4586 and other, more specific IOPs, at both the message level and the higher level protocol session levels. Complex DLI message dialogs can be monitored and system interaction sequencing verified as 4586CT follows user-defined test programs. As 4586CT can function as a proxy for other unmanned system components, it is also used during system development and task-specific integration testing and can provide insight into unmanned systems interaction and performance. Multiple instances of 4586CT can also be employed to perform rapid prototyping of interoperation protocols during profile design; as a result, 4586CT can be a useful tool during the development of interoperability standards themselves.

Future Airborne Capability Environment (FACE)

Near Term. The Army COE is an approved set of computing technologies and standards that enable secure and interoperable applications to be rapidly developed and executed across a variety of computing environments. Within the COE initiative, FACE is Army Aviation's implementation. The objective of FACE is to establish a standard COE to support portable, capability-based applications across DoD avionics systems.

FACE will reduce lifecycle costs and time to field, obtain industry and DoD program management endorsement, and facilitate conformance with standards to maximize interoperability between applications within the avionics system. The environment builds on OAs, integrated modular avionics, and a modular open systems approach (MOSA) and is designed to be portable, modular, partitioned, scalable, extended, and secure. By expanding on the MOSA and OA principles, FACE uses abstraction layers at key interfaces to diminish the need for new standards. The FACE technical strategy is to create a software environment on the installed computing hardware of DoD aircraft that enables FACE applications to be deployed on different platforms with minimal to no impact to the FACE application.

SPIES Initiative

Near Term. The goal of the SPIES initiative is to develop EO/IR sensor-platform interface standards that enable reduced acquisition, integration, and lifecycle costs; improve agility; promote OA and interoperability objectives via Navy/DoD standardization; and maintain system performance, reliability, maintenance, and availability.

SPIES will also work to enable a methodology and process for maintaining and revising the standards and adding new standards, as required. By following the computer peripheral model, the intent is for all devices and components to operate over standard buses and use standard connectors and basic database protocols. With SPIES, the expected total ownership cost savings is expected to be around 25%, with additional benefits, including reduced integration risk.

IOPs Defined for UGS

As payloads, sensors, software, and computing devices are anticipated to evolve much faster than base platforms, creating interoperable interfaces for enhanced modularity represents

4010 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

an opportunity to minimize future lifecycle costs and adapt rapidly to changing threats or new available technologies. The RS-JPO I-IPT, formed in 2009, is working to establish, adopt, and apply interoperability standards for UGS by working with the combat developers, the S&T community, and private industry. The effort is focused around utilization of the SAE AS-4 standard for JAUS with the implementation guidance being defined by the UGS IOP.

Near Term: IOP V0. In December 2011, the IOP v0 development process and content were presented to a joint executive board, consisting of Government leaders from the material developer, combat developer, and S&T communities. The joint executive board voted unanimously to approve and publish IOP V0. The IOP enables tailoring based on the use of interoperability attributes. Not every interoperability requirement will apply to every future system; therefore, the IOP provides a mechanism to independently specify these requirements in a composable manner. Interoperability attributes applicable to the specification and design of a system can be identified and used to filter applicable requirements from the IOP to support system design, development, conformance, and validation testing, IOT&E, and fielding. This approach shrinks the "design space" of future UGS interfaces from infinite to a small number of options. RS-JPO will require the use of IOPs in future requests for proposals for PORs. For industry, this interoperability approach means that companies with business models that favor closed-architecture products will ultimately either lose market share or need to adapt their business strategies. In the near term, the core interoperability team within RS-JPO and the Tank and Automotive Research, Development, and Engineering Center will be defining program- and system-specific instantiations of IOPs. Program-specific IOP instantiations will become part of future IOPs, and system-specific instantiations of IOPs will be used to determine whether there is any supporting business case to upgrade existing fielded systems to be fully or partially IOP compliant.

Middle Term: IOP V1. In addition to the capabilities already resident in widely fielded systems, IOP V1 will include interfaces for unmanned applique kits, explosive detection and marking payloads, modular controller interfaces, and a basic interface with SUAS assets. In IOP V1, the focus will be on increasing the interoperability with other domains, such as overarching networks, UAS, and manned systems.

Long Term. Future UGS are anticipated to interface with tactical and enterprise networks, such as GIG. The Army has defined a strategy for realizing a COE network into which UGS are anticipated to eventually interface. While achieving this interface would entail significant acquisition challenges in terms of information assurance planning, this interface would provide great opportunities for increasing the capabilities of UGS for warfighters. For example, a warfighter equipped with a COE-connected mobile device could search for software applications that are needed to conduct the mission, including UGS video feed and sensor-control applications. In addition, geospatial models and other data structures available in the COE could significantly enable UGVs to navigate autonomously. Autonomous operations could reduce the amount of computing power necessary on platforms and controllers and may reduce the wireless communication bandwidth required in UGS radios.

DoD will also increase coordination between ground and air domains. Although UAS and UGS are based on different standards (NATO STANAG 4586 for large UAS and SAE AS-4 (JAUS) for UGS), it is feasible for future systems to use an inward (ground) facing SAE AS-4 protocol and an outward (air) facing NATO STANAG protocol to interoperate. In addition, as

4011 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

UGS become more accepted and embedded in the force structure, interoperability with manned ground systems will be necessary. It is anticipated that the vehicular integration for C4, ISR, and EW interoperability (VICTORY) standard will provide the interoperable interfaces for communicating with manned ground systems. As a result, RS-JPO's interoperability profiles must eventually define the protocols for interfacing with VICTORY-based systems.

AEODRS Common Architecture

Currently, fielded EOD robotic systems are modified commercial products with different OCUs, limited autonomy, different architectures and designs, and company proprietary software. AEODRS is being executed by the Naval Explosive Ordnance Disposal Technology Division via the Navy Program Office for Explosive Ordnance Disposal (PMS 408) to provide joint forces with an improved and modular EOD capability to respond to unexploded ordnance, counter-improvised explosive devices, and WMD missions. AEODRS comprises three system variants, utilizing Government-owned common system architecture and interfaces, which will be fielded in an incremental approach. The common architecture is present at the physical, electrical, and logical interface levels for the UGS FoS to enable modular plug-and-play components and interoperability.

Near Term: Intraplatform Modularity. AEODRS Increment 1 is partitioned into nine separate capability modules (CMs) designed to function as standalone components across the variant platforms in the family of vehicles. Each CM is task and function specific and is designed to perform specific functions within the overarching system. Because major interfaces are defined and available to CM and subsystem competitors, the OA model aims to promote future technology infusion in a truly competitive environment. Increment 1 is broken down into three major subsystems including the OCU, the UGV, and the communication link. CMs within the UGV include CM-MOB (mobility), CM-PWR (power), CM-MAS (master), CM-MAN (manipulator), CM-VIS (vision), CM-EEF (end effector), and CM-AB (autonomous behaviors).

Middle Term: Interplatform Modularity/Interoperability. The AEODRS program consists of an FoS including three system variants that will be fielded in an incremental approach. Increment 1 (dismounted operations) will be fielded first, followed by Increment 2 (tactical operations) and Increment 3 (base/infrastructure operations). Use of common architectures and task- and function-specific capability modules will enable use of modules, software, and OCUs across platforms for all three system variants. The OA throughout the FoS allows interoperability between platforms through Government-defined and -controlled electrical, physical, and logical interfaces, in addition to the commonality of the OCU. In addition, the FoS is characterized by interchangeable modules that can be integrated in plug-and-play fashion without proprietary issues for each subsystem.

Interface Standards and IOPs

DoD has long recognized the value in fostering collaboration among Government, industry, and academia in open unmanned systems to address interoperability and common standards. To that end, a number of IPTs, WGs, and other communities have formed to address the interoperability challenge. These forums for unmanned systems have enabled the Government to engage with industry at all levels to aid in the systems and architecture design process, rather than just be customers. These collaborating communities exist within a variety of

4012 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

national and international standards bodies, span the domains of unmanned systems (air/ground/maritime), and address key cross-domain areas as well as domain-unique capabilities. DoD intends to continue to support this type of collaboration as it fosters the development of interoperability and standards WGs. Examples include the following:

- NATO Joint Capability Group Unmanned Aerial Vehicle (JCGUAV) is engaged in interoperability efforts in unmanned aviation. JCGUAV subsumed NATO's three military department UAS-related groups (i.e., PG-35, Air Group 7, and Task Group 2) in 2006. Its major accomplishments to date include NATO STANAG 4586 for UAS message formats and data protocols, NATO STANAG 4660 for interoperable C2 links, NATO STANAG 4670 for designated UAS operators training, and NATO STANAG 4671 for UAS airworthiness, and NATO STANAG 7085 for the CDL communication system, which has been mandated by OSD since 1991.[93]
- Current USIPs produced by the I-IPT define the standard interface for payload products and the data link between a control station and air vehicle for LOS and BLOS scenarios. Future USIPs will address other aspects of interoperability, including data encryption, different data link technologies such as BE-CDL, and enhanced capabilities provided by future sensors.
- JAUS began in 1995 as an effort by the Army's program office for UGS in the Aviation and Missile Research, Development and Engineering Center (AMRDEC) at Redstone Arsenal to establish a common set of message formats and data protocols for UGS made by various manufacturers. Deciding to convert JAUS to an international industry standard, the program office approached the SAE, a standards development organization (SDO) with robotics experience, which established the AS-4 Unmanned Systems Committee in August 2004. The AS-4 committee has three subcommittees focused on requirements, capabilities, and interfaces and an experimental task group to test its recommended formats and protocols before formally implementing them. The migration to the SAE has been completed, and the first set of SAE JAUS standards, focusing on the JAUS Service Interface Definition Language, core services, mobility services, manipulation services, and environmental sensing services, has been balloted and released. Although AS-4 committee members may create standards on other aspects of unmanned systems beyond message formats and data protocols for UGS, much of this broader work is now being undertaken by other UAS-related SDOs. NATO STANAG 4586 is unmanned aviation's counterpart to JAUS.

[93] NATO STANAG 4660, Standard for UAV Interoperable Command and Control Data Link (IC2DL); NATO STANAG 4670, Recommended Guidance for the Training of Designated Unmanned Aerial Vehicle Operators; NATO STANAG 4671, Unmanned Aerial Vehicle Systems Airworthiness Requirements; and NATO STANAG 7085, Interoperable Data Links for Intelligence, Surveillance, and Reconnaissance (ISR) Systems, Edition 3, pending promulgation.

Appendix D UNMANNED SYSTEMS T&E CAPABILITIES CURRENT STATUS

Unmanned Aircraft Systems

UAS T&E activities are heavily leveraging existing manned air systems T&E capabilities to test unmanned systems. Capabilities are being added to address differences for T&E of unmanned systems for primarily Level 1 autonomy systems (e.g., JUAS–Mission Environment). The C2 of today's UAS is located both on the surface (land and water) and in manned aircraft. For example, the Army recently demonstrated control of a UAS from an Apache helicopter. Today, the air vehicle decision solutions are made with deterministic algorithms. As autonomy levels increase, for example, Autonomous Aerial Cargo Utility System (AACUS) Innovative Naval Prototype (Ref 3), the systems will incorporate an ever-increasing number of nondeterministic algorithms in the UAS. T&E of how and why decisions are reached by these algorithms is a challenge that requires new improved processes and resources. As UAS embody more Level 2 to Level 4 autonomy capabilities in the future, improved tools will be needed for efficiently and effectively testing these higher levels of autonomy.[94]

Unmanned Ground Systems

UGS T&E capabilities across the Services are primarily derived from manned vehicle test capabilities. These capabilities are environment and terrain specific and were successfully used in the past to verify the safety, performance, and effectiveness of early UGS, which were controlled remotely, teleoperated, or possessed very low levels of supervised autonomy. The sensing and perception capabilities of autonomous systems are increasing rapidly, and obstacles on the terrain are equal, if not more important, to safety, performance, and effectiveness as actual terrain types and geometries.

The challenges facing the operational test community will involve the safe use of UGS integrated with warfighters and manned systems during events as well as the ability to assess mission effectiveness based on a finite number of possible physical scenarios that can be efficiently construed. Warfighters are on the ground or mounted in formation with these vehicles. Before placing these systems in the presence of the warfighter, safety and performance must be proven under controlled conditions.

To date, traditional evaluations have yet to be performed with UGS. Evaluations of currently fielded systems have been based on documenting, verifying, and assessing system safety and performance capabilities, unlike traditional evaluations, which correlate a capability to a system or mission requirement. Existing evaluation techniques based on manned systems fail to adequately assess sensing, perception, and intelligent control.

It is imperative to test UGS to verify they are safe to operate among dismounted personnel and other moving vehicles. Each Service, as well as several public and private entities, offers some degree of T&E capability required to prove the safety, suitability, and effectiveness

[94] For a description of autonomy levels, see table 3 on page 46 of the Unmanned Systems Integrated Roadmap FY2011-2036: http://www.acq.osd.mil/sts/docs/Unmanned%20Systems%20Integrated%20Roadmap%20FY2011-2036.pdf.

4014 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

of future UGS. Existing ranges and test facilities have been adequate to test systems with very limited autonomous capabilities and systems operated through teleoperation.

Unmanned Marine Systems

Existing ranges are limited to support the testing of UMS in a fully autonomous mode. Long-endurance mission profiles and limited tracking coverage restrict the test envelope for comprehensive autonomous testing behavior.

UUV test capabilities remain largely centered on underwater T&E ranges familiar with weapon systems that have attributes in common with a number of UUVs. Many UUV T&E requirements can be accomplished on these traditional underwater tracking ranges, which provide accurate track, simulation/stimulation, and acoustic acquisition and some of the required bathymetry. Many of the ranges offer additional operational areas with challenging bathymetry and environmental conditions, which help meet the T&E needs for UUV missions.

Advances in power systems and autonomy and the need for extended missions of up to a month at a time are stretching the ability of current underwater tracking ranges. Extended power capabilities and a high degree of autonomy allow newer UUVs to operate over extended areas and increase the risk of loss of these very high value, one-of-a-kind, assets. The ability to maintain track or provide areas with low risk of surface and underwater target (SUT) loss is important in these future T&E events.

The ability to safely launch and recover UUVs as SUTs presents challenges for T&E. The Navy does not have submarine platforms dedicated to T&E, and the introduction of developmental systems into the operational platform is a daunting process. This situation, coupled with limited at-sea time, challenges the comprehensive testing evolutions to demonstrate the suitability of the integrated host/UUV platform to the mission.

Appendix E MANNED UNMANNED TEAMING (MUM-T) AND MUSIC

Manned-Unmanned Teaming (MUM-T)

The concept of MUM-T is to combine the inherent strengths of manned platforms with the strengths of UAS, with product synergy not seen in single platforms. MUM-T combines robotics, sensors, manned/unmanned vehicles, and dismounted soldiers to achieve enhanced situational awareness, greater lethality, improved survivability, and sustainment. Properly designed, MUM-T extends sensor coverage in time and space and provides additional capability to acquire and engage targets.

The pilot can use the sensor on the UAS, just as a sensor would be used aboard an aircraft, except that the position of the UAS sensor can be up to 80 km ahead from the aircraft. The MUM-T capability provides an unprecedented standoff range from threat weapons and acquisition systems. MUM systems largely depend on mission, enemy, terrain, troops, time, and civil considerations. The transfer of sensor data between the UAS and the manned system reduces risk to both platforms and increases the mission effectiveness and survivability rates of friendly forces. Environmental conditions affect the efficiency of MUM-T employment.

Manned Unmanned Systems Integration Capability (MUSIC) Exercise

Interoperability has been a top objective of the Army and the UAS project office for years. Interoperability greatly increases efficiency in Army systems through common interfaces and shared assets. Development, integration, and testing of interoperability standards into UAS universal products, such as the universal GCS and the universal ground data terminal, are top objectives of the UAS project office in the near term. In an effort to streamline and coordinate interoperability initiatives across products, the UAS project office, under oversight of PEO Aviation, hosted its first MUSIC exercise in September 2011 with plans to continue conducting exercises every two years or as needed.

The MUSIC exercises showcase to the soldier and Army community the progress being made in unmanned interoperability and emerging technologies through common interfaces. Exercises also act as a strategic planning tool by driving integration and test of the various platforms to a common hardware and software baseline.

MUSIC I Exercise

Overview. The objective for the MUSIC I Exercise was to showcase interoperability progress and emerging technologies in accordance with the 2.x series of the Army UAS IOPs. The exercise took place in Dugway Proving Grounds, Utah, at the UAS Rapid Integration & Acceptance Center on 16 September 2011. Weeks of pre-ground and -flight checks culminated into a live two-hour demonstration to a group of media, contractors, and Army officials. The audience witnessed real-time video feeds from the unmanned and manned payloads, screen captures from the GCSs, video feeds from within the shelter, and visual aids through an operational scenario to help demonstrate the capabilities and achieve a better understanding of how they benefit the soldier. Successful execution of the MUSIC exercise provided the product office with a wide range of lessons learned across multiple areas, including system usability, reliability, integration, and configuration control.

4016 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Capabilities. MUSIC I showcased four main capabilities as outlined in Figure 41 and Table 2.

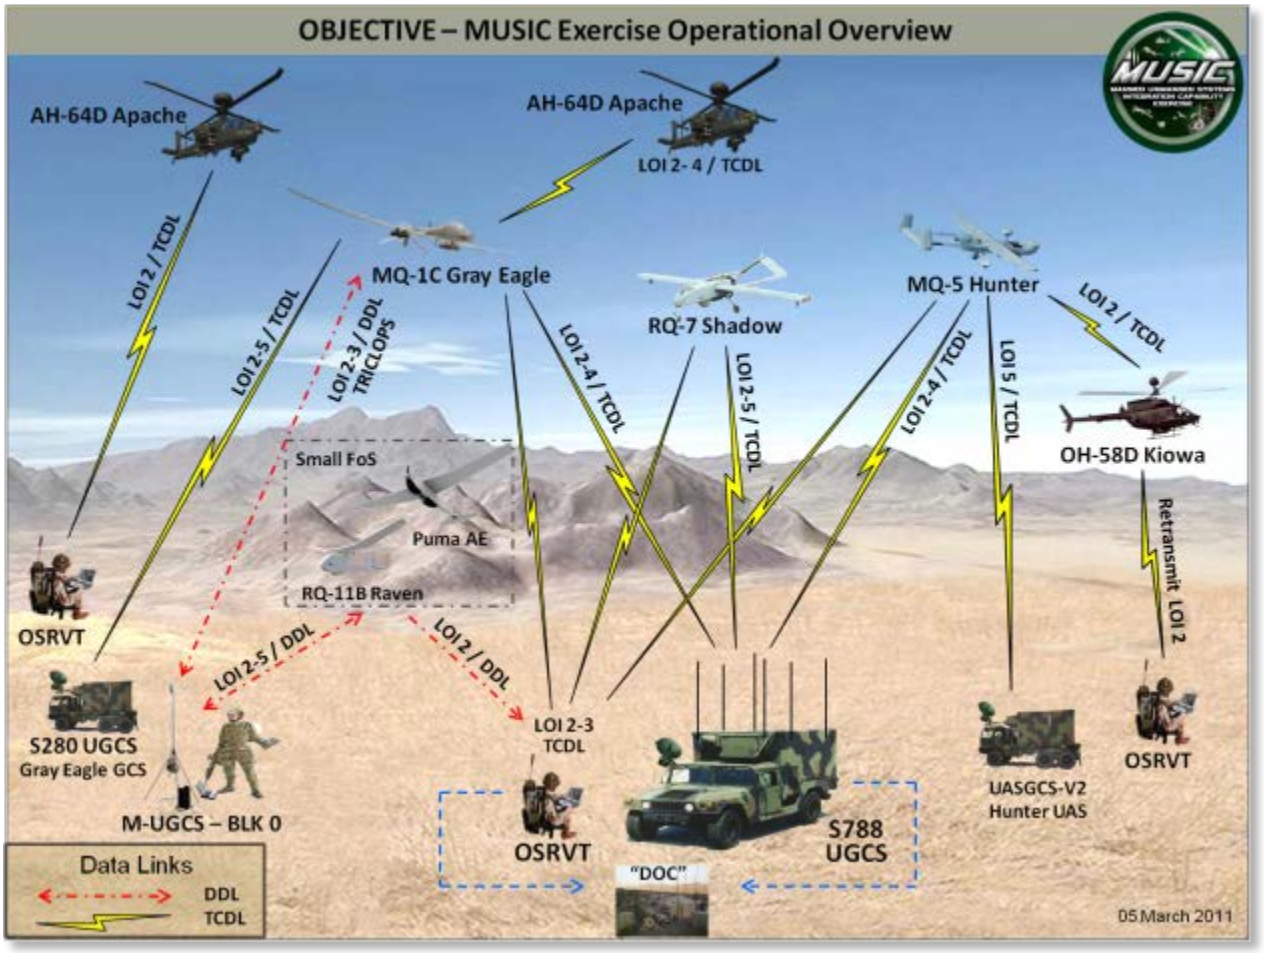

Figure 41. MUSIC I Operational View (OV-1)

4017 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Table 2. MUSIC I Capabilities and Use Cases

Capability	Description	Use Case
Universal Ground Control Station (UGCS)	A single ground control station with common hardware and software for each of the large AV, Gray Eagle, Shadow, and Hunter with the ability to consecutively control each of the large aircraft through an IOP compliant exclusive control handover sequence	Shadow UGCS control of a Gray Eagle AV via a class B handover from a Gray Eagle native GCS
		Shadow UGCS control of a Hunter AV via a class B handover from a Hunter native GCS
		Shadow UGCS control of a Shadow AV
Bi-Directional One System Remote Video Terminal (OSRVT)	A BI-directional capability that allows the OSRVT operator the ability to control the payloads on the large UAVs under supervised through an IOP compliant handover sequence	OSRVT control of the Gray Eagle Payload
		OSRVT control of the Shadow Payload
		OSRVT control of the Hunter Payload
Manned-Unmanned Teaming (MUM-T)	The ability to partner with Army Aviation manned platforms through the sharing of video.	Kiowa Warrior retrans through the Hunter AV to extend the range to the OSRVT operator on the ground
		Apache BLK II receipt of UAS video in Apache cockpit
		OSRVT receipt of Apache BLK II payload video
		OSRVT receipt of Kiowa Warrior payload video
Mini-Universal Ground Control Station/TRICLOPS	A common controller for the Small UAS, Raven and Puma, via the Digital Data Link as well a control of Gray Eagle TRICLOPS payloads. TRICLOPS payloads are two additional payloads on the wings of the Gray Eagle that can be accessed independently from the main payload by M-UGCS operators on the ground.	M-UGCS control of Raven
		M-UGCS control of Puma
		M-UGCS control of Gray Eagle TRICLOPS payloads

Appendix F CASE STUDY MQ-9 REAPER

Need to Transition from CLS to Long-Term Organic Capability

The MQ-9 Reaper program began as a quick reaction capability program in October 2001. Due to the urgency to deliver the system to the field, much of the sustainment planning was skipped. The program manager determined a CLS sustainment strategy for the life of the program. After a review, based on the statutory requirements of 10 USC 2464, the Commander, Air Force Materiel Command, determined that core capability requirements were applicable to the MQ-9 and issued a core depot decision memorandum (6 August 2008). The MQ-9 program was directed to transition into the organic depot-maintenance support.

The Reaper program also relied on CLS for field-level support because of the speed with which it was fielded. As the projected number of deployed capabilities increased, this sustainment strategy proved unaffordable. The Air Force needed to transition to military maintainers. Since the program was erroneously designated CLS for life, the program manager had not developed a data strategy or established the Government's requirements and rights for technical data. The MQ-9 was dependent on OEMs for sustaining engineering support and supply support. Initial funding estimates for data and equipment to accomplish the transformation to organic depot were also not affordable in the Air Force budget.

Initial Reliability Requirements Not Met

Typical of many programs that have been rapidly developed and deployed, the reliability requirements of the Reaper system were initially not well understood or developed. The primary reliability metric being measured and tracked was mean time between critical failure (MTBCF) as documented in the CPD of August 2006. This metric received a deferment from the Air Force Requirements Oversight Council after the 2008 IOT&E report noted the original MTBCF values were not achievable based on system performance. Additionally, because of the lack of redundant systems, all failures were interpreted as "critical failures." In 2011 it was recognized that deferring the achievement of the reliability goal until a future block upgrade would not be sufficient. The Air Force needed to reevaluate the requirement against test and operational data to determine a realistic reliability goal and then establish a reliability growth program to ensure that the system could continue to meet the goal.

Sustainment Transformation

Since 2009, the program office has been executing a strategy to transform the sustainment of the Reaper program to focus on long-term affordability. The transformation planning by the program office culminated in the development of a lifecycle sustainment plan that details the results of the program's planning efforts and documents the overall framework for optimal sustainment of the MQ-9 system throughout its life cycle at minimum lifecycle cost. The plan emphasizes the following major elements: requirements stability and reliability growth, depot transition, data strategy, and business case analysis (BCA).

Requirements Stability/Reliability Growth

The program established a Joint Reliability Maintainability Evaluation Team in 2012. The team reviewed field failure data and made recommendations to the warfighter community

4019 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

for new Threshold and Objective MTBCF values. The MQ-9 reliability and maintainability growth program has been established to manage the growth of reliability with an emphasis on identifying reliability readiness and cost drivers that have a substantial return on investment to the warfighter.

Depot Transition

10 USC 2464 (a)(3)(B) states the requirement, "Core depot-level maintenance and repair capabilities and capacity, including the facilities, equipment, associated logistics capabilities, technical data, and trained personnel, shall be established not later than four years after a weapon system or item of military equipment achieves initial operational capability or is fielded in support of operations."[95] In December 2009, the program established the Depot Maintenance Actions Working Group (DMAWG) to stand up organic repair. A three-phased approach was established to target the major repair and cost drivers:

- The first phase, Early Induction, identified items with low activation risk and includes the MQ-9 EO/IR sensors and a selection of items from the aircraft, engine, and communication equipment. The initial induction program will stand up in FY2013.
- The second phase will expand the initial partnership to cover items that generate 80% of the repair costs and will be put in place between 2014 and 2015, seven years after core was first determined to be applicable.
- The final phase will include more than 500 components with low repair rates.

Throughout the DMAWG process, the program is working with the Army Gray Eagle program to identify opportunities for leveraging similar efforts. The programs are working together to establish sensor capability with the Navy's Fleet Repair Center South East in Jacksonville, Florida.

Data Strategy

PPPs between OEMs and depots is one method to assure that the Government will have access to repair data without requiring a procurement or re-procurement data package. In addition to pursuing these partnerships, the Reaper program office continues to pursue Government ownership of data and is leveraging the Army Gray Eagle program's research of the Government's rights.

The program continues to provide contractor field service representatives (FSRs) while developing interactive electronic technical manuals, which will greatly enhance the military organization-level maintainer's ability to troubleshoot and repair the system while reducing the need for contractor FSRs and depot-level field assistance.

Business Case Analysis (BCA)

In December 2009, the program began a BCA to recommend a long-term sustainment strategy for the MQ-9 weapon system. The scope of the analysis included a full evaluation of the MQ-9 sustainment alternatives, including the implementation of performance-based logistics,

[95] As amended by P.L. 112-81 in 2011. Previously there was a requirement to identify core capability within four years of IOC.

4020 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

initiation of PPPs, and the evaluation of organic sustainment support. A baseline report was presented in July 2010. After a strategic pause to incorporate critical repair data and lessons learned from other BCA efforts, the MQ-9 BCA effort resumed in May 2011 and was completed in June 2012. The final BCA recommended separate performance-based agreements for the sensors, aircraft, and engine between the OEMs and depots and recommended that supply chain management be transitioned to the Government. See Figure 42.

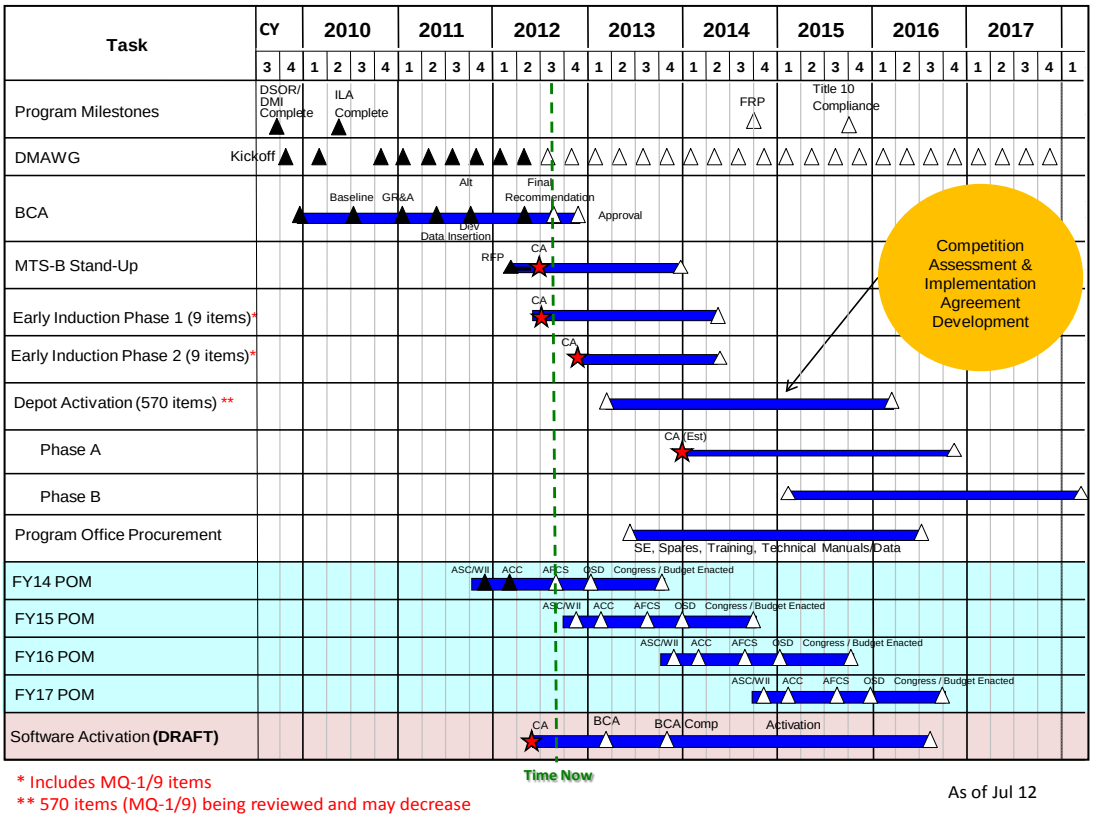

Figure 42. MQ-9 Reaper Sustainment Plan

Conclusion

The MQ-9 Reaper case study illustrates the strategy and actions required, when proper initial lifecycle sustainment planning was not done, to transform the sustainment of unmanned systems from a short-term, rapid-fielding environment to a long-term sustainment environment. The transformation of unmanned systems will require dedicated effort over the next decade to develop and execute lifecycle sustainment strategies that ensure the long-term affordability of the systems. In the case of the Reaper program, the lifecycle sustainment strategy end state of organic support is expected to be fully achieved by 2018 — almost 10 years after the Air Force established the requirement and many years after statutory mandates. As new programs are developed, it is critical for programs, in conjunction with their Services and warfighters, to begin to formulate a lifecycle sustainment strategy at program inception so that requirements for availability, reliability, and affordability are considered in the design, sustainment resources are identified early, product support packages are tested with the system, and long periods of interim contractor support are avoided once the programs are fielded.

GAO Highlights

Highlights of GAO-14-340SP, a report to congressional committees

March 2014

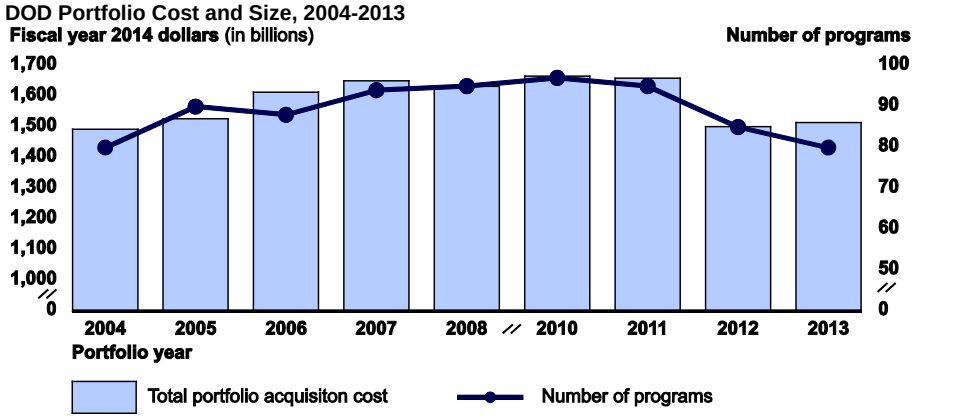
DEFENSE ACQUISITIONS

Assessments of Selected Weapon Programs

Why GAO Did This Study

This is GAO's annual assessment of DOD weapon system acquisitions, an area that is on GAO's High-Risk List. DOD and Congress have taken meaningful steps to improve the acquisition of major weapon systems, yet many programs are still falling short of cost and schedule estimates. Moreover, GAO has emphasized the importance of completing developmental testing before programs enter production and pointed out risks associated with such concurrent testing and production. With expected budgetary pressures, DOD cannot afford to miss opportunities to address inefficiencies in these programs to free up resources for higher priority needs.

This report responds to a mandate in the joint explanatory statement to the DOD Appropriations Act, 2009. It includes observations on (1) the cost and schedule performance of DOD's 2013 portfolio of 80 major defense acquisition programs; (2) the knowledge attained at key junctures in the acquisition process for 38 programs that were in development or early production; and (3) key acquisition reform initiatives and program concurrency. To develop the observations in this report, GAO analyzed cost, schedule, and quantity data from DOD's Selected Acquisition Reports. GAO also collected data from program offices on technology, design, and manufacturing knowledge; the use of knowledge-based acquisition practices; and the implementation of acquisition reforms and initiatives.



In commenting on a draft of this report, DOD cited its commitment to acquisition excellence and its positive effect on programs.

View GAO-14-340SP. For more information, contact Michael J. Sullivan at (202) 512-4841 or sullivanm@gao.gov.

What GAO Found

Over the past year, the overall size of DOD's major defense acquisition program portfolio decreased, from 85 programs to 80, while the estimated cost has increased by $14.1 billion. The average time to deliver initial capability to the warfighter also increased by 2 months. The slight cost increase can be attributed to the addition of one program, the Evolved Expendable Launch Vehicle. This furthers a trend for decreased portfolio size seen for the past three years. Although the overall cost of the 2013 portfolio increased, 50 of the 80 programs decreased costs, and 64 percent of programs increased their buying power. There are still some programs that have performed poorly, both over the past year and in the longer term. Fifty-five percent of the current portfolio funding has been appropriated, leaving approximately $682 billion needed for future funding. About forty-five percent of this remaining funding represents cost growth from initial estimates, a clear indicator that DOD needs to do more to control cost growth.

DOD Portfolio Cost and Size, 2004-2013

Source: GAO analysis of DOD data.
Note: The 2009 portfolio is excluded as the appropriate data was not available for review.

Most of the 38 programs GAO assessed this year are not yet fully following a knowledge-based acquisition approach. This held true for the seven programs that passed through one of three key decision points in the past year. Each implemented some knowledge based practices but practices—such as fully maturing technologies prior to development start and bringing all manufacturing processes under control—were not implemented. As a result, many of the 38 programs will carry unwanted risk into subsequent phases of acquisition that could result in cost growth or schedule delays.

Implementation of the reform initiatives on the 38 programs assessed above, and 18 that are not yet major defense acquisition programs, GAO analyzed varies. Specifically, while the department has been successful in implementing its "should cost" initiative to reduce contract costs and established configuration steering boards, the establishment of limits on total program costs (i.e. affordability constraints) and the need for greater competition are not being implemented to the same degree. In addition, many programs continue to commit to production before completing developmental testing.

Comptroller General of the United States

441 G St. N.W.
Washington, D.C. 20548

March 31, 2014

Congressional Committees

I am pleased to present GAO's 12th annual assessment of the Department of Defense's (DOD) major defense acquisition programs. This report offers observations on the performance of DOD's current $1.5 trillion portfolio of 80 programs. At its current size, this portfolio will require almost one-third of all expected development and procurement funding during the next 5 years. With the decline in the availability of discretionary funding, DOD cannot afford to miss opportunities to address inefficiencies in these programs to free up resources for additional high priority needs such as support of current operations. Consistent with our past recommendations, Congress and DOD have taken meaningful steps over the past several years to address long-standing problems with DOD weapon system acquisitions—an area that has been on GAO's high-risk list for more than 20 years.[1] We are encouraged about these steps, but we are also mindful that previous attempts to implement best practices and reign in cost and schedule overruns have failed or resulted in only marginal improvements.

Our current assessment shows that the estimated cost of DOD's 2013 portfolio of major defense acquisition programs is $14.1 billion more than the 2012 portfolio while the size of the portfolio decreased from 85 to 80 programs.[2] This places the size and cost of the portfolio on par with what it was for the 2004 portfolio, as opposed to the peak in size and cost seen in the $1.7 trillion, 97-program portfolio in 2010. Over the past year, the 80 programs of the 2013 portfolio have grown by a total of $12.6 billion, a net cost increase nearly all attributable to the significant procurement cost associated with one program—the Evolved Expendable Launch Vehicle. The cost growth of the portfolio as a whole is not necessarily indicative of the performance of every program as 50 of the 80 programs reduced their

[1]GAO, *High-Risk Series: An Update*, GAO-13-283 (Washington, D.C.: February 2013).

[2]Our assessment of DOD's 2012 portfolio of 86 major defense acquisition programs included the Missile Defense Agency's Ballistic Missile Defense System (BMDS). While DOD continues to report on BMDS as a major defense acquisition program, we exclude it from our assessment this year as the program lacks an acquisition program baseline comparable to the other programs, preventing us from measuring cost and schedule change in a manner consistent with our methodology. For more information on cost and schedule baselines for BMDS and the challenges for oversight they present see GAO, *Missile Defense: Opportunity to Refocus on Strengthening Acquisition Management*, GAO-13-432 (Washington, D.C.: Apr. 26, 2013).

4041 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

costs over the past year. While a large number of programs did reduce cost over the past year, the need for continued oversight and cost management remains as many programs are still not achieving the long-range targets for limited total acquisition cost growth discussed by GAO, DOD, and the Office of Management and Budget. Our assessment also shows that the implementation of knowledge-based acquisition practices varied across the portfolio, though programs that entered over the past 5 years were more likely to follow knowledge-based principles at development start thereby making them more likely to achieve their cost, schedule, and performance objectives. Finally, our analysis shows that many programs are implementing selected acquisition reforms focused on affordability and cost savings, although DOD continues to accept risks by allowing programs to begin production before completing developmental testing. This report also includes brief assessments of 56 future and current major defense programs that provide additional insights into the performance of the portfolio.

Current and anticipated fiscal constraints make it imperative that DOD continue to find ways to improve the efficiency of its major weapon systems portfolio while still delivering the capabilities required by the warfighter. While many of the recent efficiencies achieved by programs decreased their costs without reducing quantities, it is unclear how much more savings can be obtained in this manner or if the estimates of future saving based upon ongoing DOD efficiency initiatives will come to fruition. Continued strong leadership on the part of DOD is essential, whether on advancing gains made through “Better Buying Power” initiatives or in enforcing a broader implementation of best practices in all aspects of a new weapon system acquisition as it enters the portfolio.

Congressional Committees

In response to the mandate in the joint explanatory statement to the Department of Defense Appropriations Act, 2009, this report provides perspectives on how well the department is planning and executing its $1.5 trillion portfolio of major weapon programs, in addition, this report includes information related to small business participation pursuant to a mandate in a report accompanying the National Defense Authorization Act for Fiscal Year 2013.[1] The current portfolio's cost has declined since peaking at $1.7 trillion in 2010 and is currently at its lowest point in almost 10 years. In addition, the number of programs in the portfolio has decreased from 97 in 2010 to 80 programs in 2013. Since the first issuance of this series of reports in 2003, Congress and DOD have made meaningful improvements to the statutory and policy frameworks that govern the defense acquisition system by mandating and encouraging a more knowledge-based approach for major weapon programs. However, we have noted in the past that practice has lagged behind policy in certain areas and commensurate improvements in program outcomes are often not evident as many programs continue to cost more and take longer to develop than originally estimated. The changes in DOD's portfolio over the past few years indicate that some improvements are being realized in the near term. With the prospect of decreased defense budgets in the near future, it is imperative that DOD continue to find ways to reduce cost and improve the economy and efficiency of its acquisition practices not only in the short term, but throughout the life of current and future defense acquisition programs. Such cost reductions may be found by changing program acquisition strategies to include a more knowledge-based approach through the implementation of acquisition reforms and initiatives and the reduction of practices like concurrent testing and production, the risks of which we have identified repeatedly.

This report includes observations on (1) the cost and schedule performance of DOD's 2013 portfolio of 80 major defense acquisition programs, (2) the knowledge attained at key junctures in the acquisition

[1]See Explanatory Statement, 154 Cong. Rec. H 9427, 9526 (daily ed., Sept. 24, 2008), to the Department of Defense Appropriations Act, 2009, contained in Division C of the Consolidated Security, Disaster Assistance, and Continuing Appropriations Act, 2009, Pub. L. No. 110-329 (2008) and H.R. Rep. No. 112-479, at 284 (2012), *accompanying* Pub. L. No.112-239.

4043 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

process for 38 weapon programs in development or early production, and (3) key acquisition reform initiatives and whether programs are conducting or planning concurrent testing and production.[2]

Our observations in this report are based on three sets of programs:

- We assessed 80 major defense acquisition programs in DOD's 2013 portfolio for our analysis of cost and schedule performance. We obtained cost, schedule, and quantity data from DOD's December 2012 Selected Acquisition Reports (SAR) and from the Defense Acquisition Management Information Retrieval Purview system.

- We assessed 38 major defense acquisition programs that were mostly between the start of development and the early stages of production for our analysis of knowledge attained at key junctures and the implementation of acquisition reforms. We obtained information on the extent to which the programs follow knowledge-based practices for technology maturity, design stability, and production maturity using a data-collection instrument. We also submitted a questionnaire to program offices to collect information on issues such as systems engineering reviews, design stability, manufacturing planning and execution, and the implementation of specific acquisition reforms. We received questionnaire responses from all 38 programs from August to November 2013.

- In addition, we assessed 18 future major defense acquisition programs in order to gain additional insights into knowledge attained before the start of development and the implementation of key acquisition reform initiatives. We submitted a questionnaire to program offices to collect information on issues such as program schedule events, costs, and numerous acquisition reforms, and received responses from all 18 programs from August to November 2013.

[2]Major defense acquisition programs (MDAP) are those identified by DOD with a dollar value for all increments estimated to require eventual total expenditure for research, development, test, and evaluation of more than $480 million, or for procurement of more than $2.79 billion, in fiscal year 2014 constant dollars. DOD has a list of programs designated as future major defense acquisition programs. These programs have not formally been designated as MDAPs; however, DOD plans for these programs to enter system development, or bypass development and begin production, at which point they will likely be designated as MDAPs. We refer to these programs as future major defense acquisition programs throughout this report.

4044 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

In addition to our observations, we present individual assessments of 56 weapon programs. Selection factors include major defense acquisition programs in development or early production, future programs, and recently canceled or restructured programs.

We conducted this performance audit from June 2013 to March 2014 in accordance with generally accepted government auditing standards. Those standards require that we plan and perform the audit to obtain sufficient, appropriate evidence to provide a reasonable basis for our findings and conclusions based on our audit objectives. We believe that the evidence obtained provides a reasonable basis for our findings based on our audit objectives. Appendix I contains detailed information on our scope and methodology.

Observations on the Cost and Schedule Performance of DOD's 2013 Major Defense Acquisition Program Portfolio

The estimated cost of DOD's 2013 portfolio of 80 weapon programs is $14.1 billion more than the 2012 portfolio of 85 programs. The 80 programs within this year's portfolio have had estimated cost increases of $12.6 billion against their estimates from a year ago and an average of 2 months increase in schedule. This increase masks otherwise positive trends as 50 of 80 programs in the portfolio decreased their total acquisition costs and the majority of the cost increases can be traced to either the effects of additional procurement quantities or inefficiencies experienced in a few programs. Though notable, the cost reductions achieved by the programs in the 2013 portfolio over the past year need to be weighed against the increases many of these programs have had over the past five years or since their first full estimate of costs. Our analysis of DOD's 2013 portfolio allows us to make the following eight observations.

4045 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Cost and Schedule Performance Observations

General changes in the portfolio

1. When compared to the 2012 portfolio, the size of DOD's 2013 portfolio decreased from 85 to 80 programs, but its overall cost has increased by $14.1 billion from $1,501 billion to $1,515 billion. The decrease in portfolio size follows a trend from the past 3 years.[a]
2. When comparing the cost and schedule estimates of the 80 programs in the 2013 portfolio we found cost growth of $12.6 billion and an average schedule delay of 2 months over the past year. When assessed against first full estimates, the total cost of the 2013 portfolio has increased by nearly $448 billion with an average delay of 28 months in operating capability.[b]

Factors that explain the changes

3. While the overall cost of the 2013 portfolio has increased, 50 of the 80 programs within the portfolio reduced their costs over the past year. The majority of the net cost growth can be attributed to a single program, the Evolved Expendable Launch Vehicle (EELV).
4. Our analysis shows that, when the effects of quantity changes are accounted for, DOD improved buying power on 64 percent of the programs in the portfolio over the past year.
5. As measured against metrics discussed by GAO, the Office of Management and Budget, and DOD in 2008, only 55 percent of programs in the 2013 portfolio meet the metric for less than 10 percent growth over the past 5 years and only 44 percent meet the metric for less than 15 percent growth since first full estimates; both proportions are smaller than in the 2012 portfolio, which demonstrates that a program can experience an interval of cost stability between periodic cost increases.

Other observations

6. The total acquisition cost of the portfolio is driven in large part by the 10 costliest programs, which represent 59 percent of current portfolio's total cost. These 10 programs alone incurred a net cost increase over the past year of approximately $15.4 billion due primarily to quantity increases on the EELV, while the other 70 programs reported a net cost decrease of $2.8 billion over the same period.
7. The majority of the cost of the portfolio is concentrated in two system types and the amount and type of cost growth from first full estimate, as well as the schedule delay, varied significantly by system type.
8. DOD has already been appropriated more than $833 billion for the current portfolio, leaving approximately $682 billion in costs to be funded, mostly for procurement. Approximately 45 percent of the remaining cost represents growth from first full estimates. Almost two-thirds of the future funding is needed for 10 programs, with 35 percent of the total costs remaining required for the F-35 program alone.

[a]All dollar figures are in fiscal year 2014 constant dollars, unless otherwise noted.

[b]Total acquisition cost includes acquisition-related operation and maintenance costs and system-specific military construction costs in addition to development and procurement costs.

Additional details about each observation follow.

4046 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

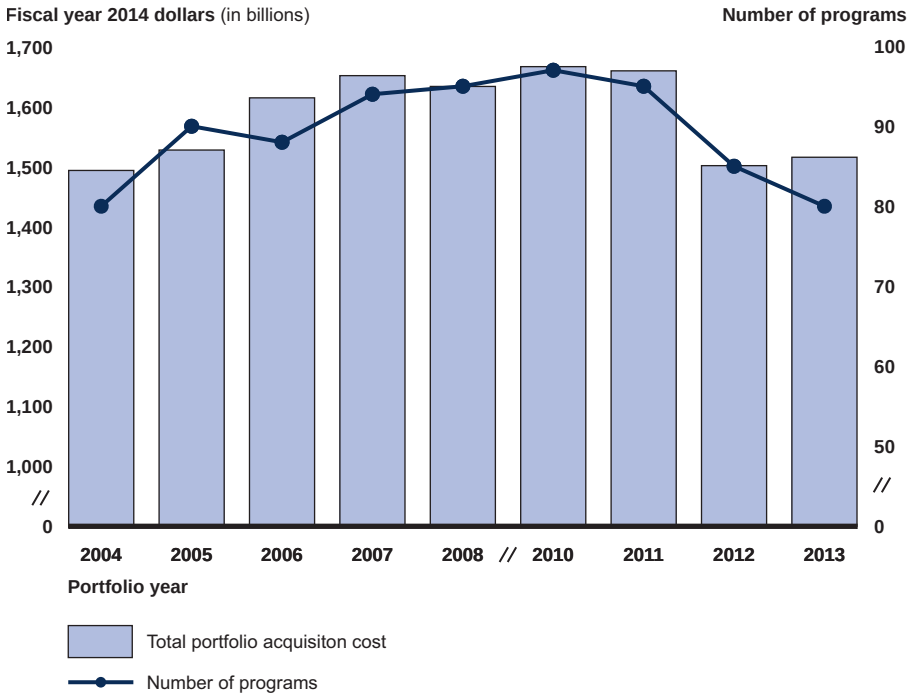
1. **When compared to the 2012 portfolio, the size of DOD's 2013 portfolio decreased from 85 to 80 programs, but its overall cost has increased by $14.1 billion, from $1,501 billion to $1,515 billion. The decrease in portfolio size follows a trend from the past 3 years.** With 80 programs and an estimated total cost of more than $1.5 trillion, the 2013 portfolio has fewer programs but a larger total acquisition cost when compared to the 2012 portfolio. The changes from the 2012 portfolio to the 2013 portfolio are outlined in table 1 below.

Table 1: Changes in DOD's Portfolio of Major Defense Acquisition Programs from 2012 to 2013

Fiscal year 2014 dollars in billions	
2012 portfolio (85 programs)	**$1,501.1**
Less cost of 12 exiting programs	-$73.1
Plus estimated total cost of 7 entering programs	+$101.6
Less net cost changes of 73 remaining programs	-$14.4
2013 portfolio (80 programs)	**$1,515.2**

Source: GAO analysis of DOD data.

Note: Our assessment of DOD's 2012 portfolio included the Ballistic Missile Defense System (BMDS). We exclude it from our assessment this year as the program lacks an acquisition program baseline comparable to other programs, preventing us from measuring cost and schedule change in a manner consistent with our methodology. To make the comparisons above we adjusted the 2012 portfolio estimates to reflect the removal of BMDS. Some numbers may not sum due to rounding.



The 2013 portfolio reflects a net reduction of 5 programs—from 85 to 80—and, when all the programmatic changes are taken into account, the cost of the 2013 portfolio is $14.1 billion more than the 2012 portfolio.[3] The current size of the portfolio in terms of number of

[3]The 12 programs that exited the portfolio were AIM-9X Block I, C-130 Avionics Modernization Program, Chemical Demilitarization-Chemical Materials Agency, Cobra Judy Replacement, High Mobility Artillery Rocket System, Joint High Speed Vessel, Joint Tactical Radio System Ground Mobile Radio, Multi-Platform-Radar Technology Insertion Program, National Polar-orbiting Operational Environmental Satellite System, Stryker Family of Vehicles, Thermal Weapons Sight, Warfighter Information Network - Tactical Increment 1. The seven that entered the portfolio were Airborne Warning and Control System Block 40/45 Upgrade, AN/TPS-80 Ground/Air Task Oriented Radar, B61 Mod 12 Life Extension Program Tailkit Assembly, Evolved Expendable Launch Vehicle, Joint Light Tactical Vehicle, Next Generation Operational Control System (GPS OCX), and Ship to Shore Connector.

4047 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

programs and total cost is similar to that seen in the 2004 portfolio and furthers a trend for decreased portfolio size, and to some extent cost, seen since the 2010 portfolio. Figure 1 shows the cost and size of DOD's portfolios of major weapons acquisitions over the past 10 years.

Figure 1: DOD Portfolio Cost and Size, 2004-2013

Source: GAO analysis of DOD data.

Note: The 2009 portfolio is excluded because there were no annual SARs released for the December 2008 submission date.

A closer look at the 7 programs that entered the portfolio shows that 4 entered the portfolio at the beginning of system development. In contrast, two of the other three programs—the AN/TPS-80 Ground/Air Task Oriented Radar (G/ATOR) and the Airborne Warning and Control System Block 40/45 Upgrade—entered the portfolio long after their development start and are in production or will have a production decision in 2013. These programs were not originally planned as major acquisitions, but their costs grew past the threshold for major defense acquisition programs. For example, G/ATOR began system development in 2005 as a non-major defense acquisition program and

4048 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

was reclassified due to program cost growth realized after completing 6 years of an 8-year development effort. The final program, EELV, re-entered the portfolio in response to statutory direction and soon after reported a quantity increase and a critical breach of Nunn-McCurdy unit cost threshold.[4]

Of the 12 programs that exited the portfolio, 8 completed development and fielded a system, while three were canceled after reporting substantial development cost growth or delays to their planned initial capability or, in one case, both. A final program, the Joint High Speed Vessel, exited the portfolio after a quantity reduction caused its cost to slip below the threshold for major defense acquisition programs.

2. **When comparing the cost and schedule estimates of the 80 programs in the 2013 portfolio we found cost growth of $12.6 billion and average schedule delay of 2 months over the past year.** While the above observation states the change from the 85 program 2012 portfolio due to programs exiting and entering, in this observation we measure the change that occurred only on the 80 programs in the 2013 portfolio. Table 2 shows the changes in cost and schedule for the 2013 portfolio in the past year.

[4]Section 2433 of title 10 of the United States Code, commonly referred to as Nunn-McCurdy, requires DOD to notify Congress whenever a major defense acquisition program's unit cost experiences cost growth that exceeds certain thresholds. This is commonly referred to as a Nunn-McCurdy breach. Significant breaches occur when the program acquisition unit cost or procurement unit cost increases by at least 15 percent over the current baseline estimate or at least 30 percent over the original estimate. For critical breaches, when these unit costs increase at least 25 percent over the current baseline estimate or at least 50 percent over the original, DOD is required to take additional steps, including conducting an in-depth review of the program. Programs with critical breaches must be terminated unless the Secretary of Defense certifies to certain facts related to the program and takes other actions, including restructuring the program. 10 U.S.C. § 2433a.

4049 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

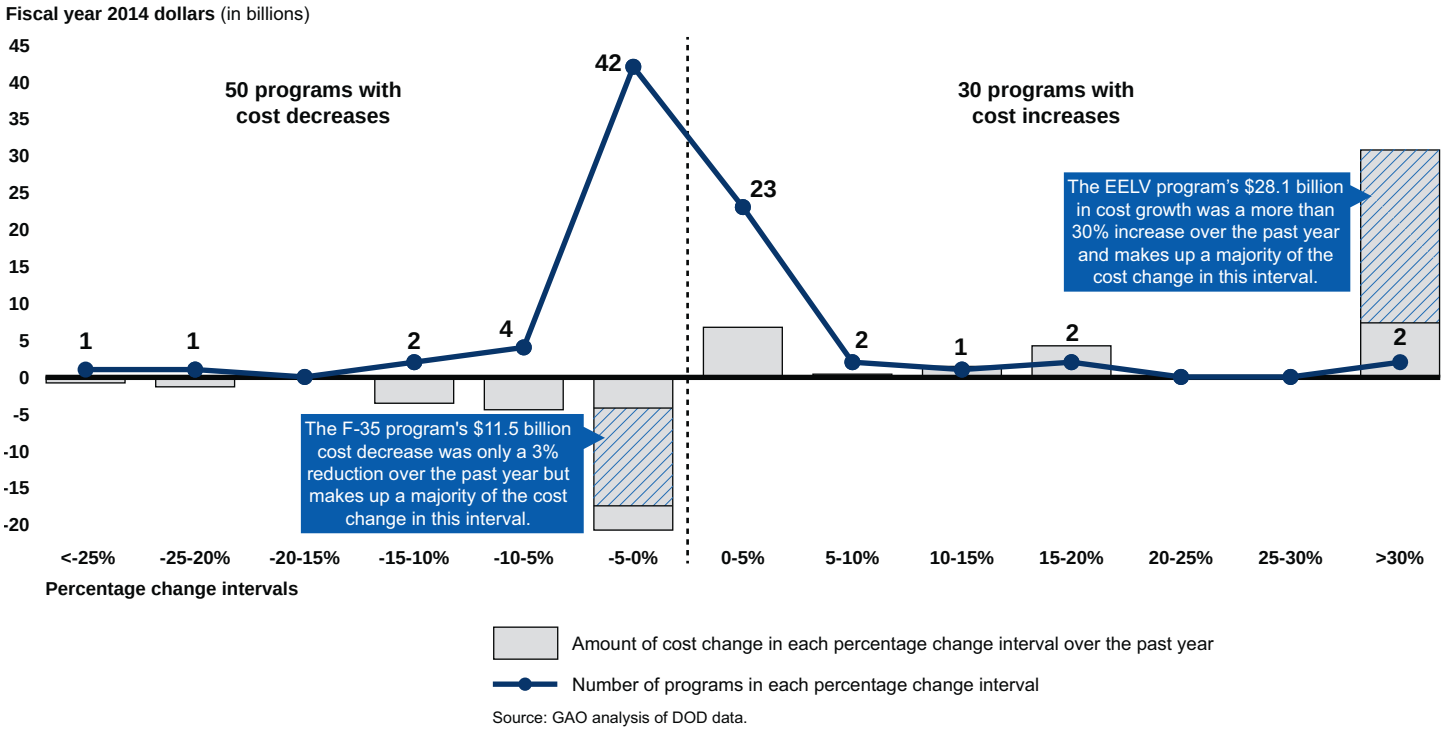
Table 2: Changes in DOD's 2013 Portfolio of 80 Major Defense Acquisition Programs over the Past Year

Fiscal year 2014 dollars in billions

	Estimated 2013 portfolio cost in 2012	Estimated 2013 portfolio cost in 2013	Increase since 2012	Percentage change since 2012
Total estimated research and development cost	$286.7	$288.7	$2.0	0.7%
Total estimated procurement cost	1,201.6	1,213.2	11.5	1.0
Total other acquisition costs[a]	14.3	13.3	-0.9	-6.3
Total estimated acquisition cost	1,502.6	1,515.2	12.6	0.8
Average delay in delivering initial capabilities	—	—	2 months	2.8%

Source: GAO analysis of DOD data.

Note: Some numbers may not sum due to rounding.



[a]In addition to research and development and procurement costs, total acquisition cost includes acquisition-related operation and maintenance and system-specific military construction costs.

The rise in total acquisition cost within the current portfolio over the past year is attributable to cost growth in both development and procurement, with procurement accounting for more than 90 percent of the total increase. Decreases in other costs, such as military construction, result in a net cost growth of $12.6 billion for these 80 programs over the past year. When measured against programs' first full estimates, the total acquisition cost of the current portfolio has grown by $447.8, or nearly 42 percent. The average delay in delivering initial capabilities has slipped an additional 2 months over the past year. The average delay against first full estimates is 28 months, on average.

3. **While the overall cost of the 2013 portfolio has increased, 50 of the 80 programs within the portfolio reduced their costs over the past year. The majority of the net cost growth can be attributed to a single program—EELV.** The $12.6 billion increase shown in table 2 above is the net result of cost changes on all 80 programs in the current portfolio. The distribution of those cost changes across the portfolio is shown below in figure 2.

4050 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Figure 2: Distribution of the Total Acquisition Cost Change for the 2013 Portfolio

Source: GAO analysis of DOD data.

Our analysis, as represented above, shows that 50 programs experienced cost decreases totaling almost $30.9 billion during the past year while 30 programs reported cost increases totaling approximately $43.5 billion. Of the programs that decreased their total acquisition costs,

- 38 did so by finding efficiencies within the program and not by decreasing procurement quantities;
- 9 reduced their procurement quantities thereby reducing overall cost; and
- 3 increased their procurement quantities but found enough offsetting efficiencies to reduce overall cost.

The most significant of these decreases is the $11.5 billion reduction to the F-35 Joint Strike Fighter program's estimate, due solely to

4051 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

efficiencies found within the program as no decrease in quantities was reported. In contrast, 30 programs reported cost increases. Of these,

- 17 reported cost increases due to inefficiencies in the program and not any change to procurement quantities;
- 12 programs increased their procurement quantities; and
- 1 program reduced estimated procurement quantities but still reported an increase to total costs.

The most significant of the programs with increases to total acquisition cost was EELV, which reported an increase in the number of launch services it expected to procure and a $28.1 billion, or 78 percent, increase in total acquisition cost during the past year. As can be seen from the preceding tally of individual cost increases and decreases, to better understand the changes to cost the effect of changes to quantity must be understood.

4. **Our analysis shows that, when the effects of quantity changes are accounted for, DOD improved buying power on 64 percent of the programs in the portfolio over the past year.** Although procurement costs for the portfolio increased by $11.5 billion over the past year, this growth is lower than GAO's calculations of the expected cost growth due to quantity changes, indicating that programs found efficiencies in other areas and increased their buying power.[5] In general, buying power can be defined as the amount of good or service that can be purchased given a specified level of funding. Our calculation of how programs' cost and quantity changes affected their buying power are presented in table 3.

[5]A description of this calculation can be found in the detailed scope and methodology in appendix I.

4052 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Table 3: Increases in Buying Power for the 2013 Portfolio over the Past Year

Fiscal year 2014 dollars in billions

	Number of programs	Actual procurement cost change	GAO-calculated cost change attributable to quantity changes	GAO-calculated cost change not attributable to quantity changes
Increased buying power	**51**	**-$23.0**	**$4.9**	**-$27.9**
Procurement cost decreased with no quantity change	35	-22.6	0	-22.6
Quantity increased with less cost increase than anticipated	10	4.8	7.9	-3.1
Quantity decreased with more cost decrease than anticipated	6	-5.2	-3.0	-2.2
Decreased buying power	**25**	**$34.5**	**$22.4**	**$12.1**
Procurement cost increased with no quantity change	16	4.7	0	4.7
Quantity increased with more cost increase than anticipated	5	32.1	25.3	6.8
Quantity decreased with less cost decrease than anticipated	4	-2.3	-2.9	0.5
No change in buying power	**4**	**$0**	**$0**	**$0**
Total	**80**	**$11.5**	**$27.3**	**-$15.8**

Source: GAO analysis of DOD data.

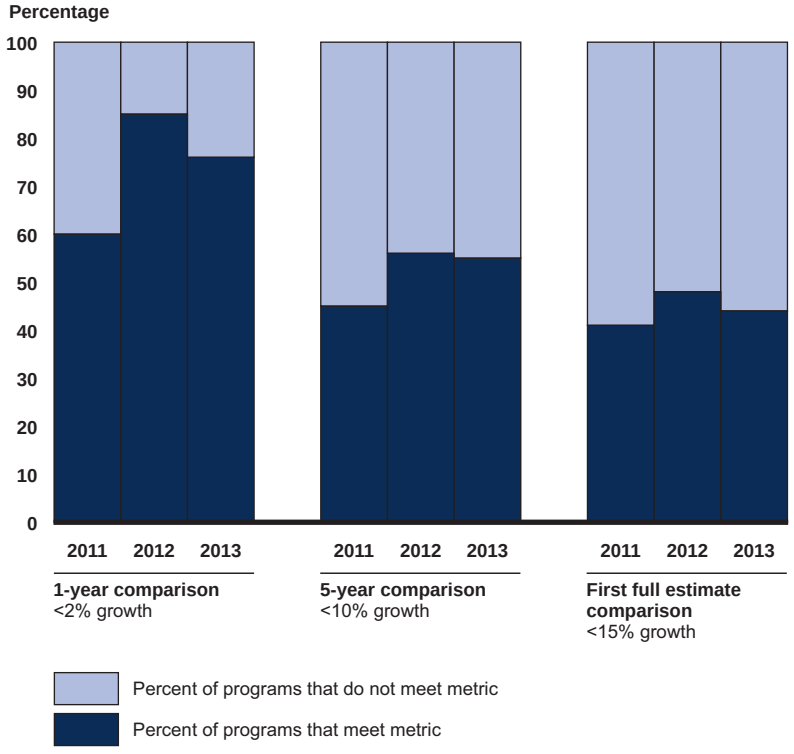
Note: Some numbers may not sum due to rounding.

Based on our analysis, a total of 51 programs increased their buying power in the past year, resulting in a total of $23 billion in procurement cost reductions. Thirty-five of the programs that decreased their procurement cost did so without reducing quantities, an indication that they found efficiencies elsewhere. Ten programs increased their expected procurement quantities but their total procurement cost increase was less than would be expected based upon the average procurement unit cost of each program used in GAO's calculation. For example, over the past year the DDG 51 program added two ships to its planned procurement, at an estimated unit cost of more than $1.3 billion. If the resulting procurement cost increase from these additional quantities is ignored the cost for the program actually decreases, due to the fact that it found efficiencies elsewhere that increased the program's buying power even as the program increased quantities. An additional 6 programs decreased their quantities but achieved cost reductions in excess of that anticipated by GAO's cost calculations. For example, the Littoral Combat Ship (LCS) program reported a procurement cost decrease of over $3 billion. While a significant portion of this reduction was achieved by removing three ships from the planned procurement, almost half, $1.2 billion, was due to factors

4053 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

other than the quantity reduction, such as a revised estimate that reflects lower future costs.

Increases in buying power such as these could be expected to continue as many of the programs that responded to our questionnaire indicated that they expected large amounts of "should-cost" savings in the future. The "should-cost" initiative, introduced through DOD's "Better Buying Power" initiatives, emphasizes the importance of driving cost improvements during contract negotiation and program execution to control costs, improvements that could lead to program efficiencies which increase buying power. For example, the AIM-9X Block II Air-to-Air Missile program realized a procurement cost decrease of approximately $327 million with no change in quantity over the past year and also reported $128 million in "should-cost" savings that are expected in the future. In another case, the MQ-4C Triton Unmanned Aircraft System also realized decreasing procurement costs of $274 million over the past year while maintaining the same quantity and reported that another $480 million in "should-cost" savings are expected in the future.



Our analysis in table 3 above also shows that procurement costs for 25 programs increased by $34.5 billion, but by our calculation only $22.4 billion can be attributed to the cost of procuring additional units, with $12.1 billion of that increase attributable to other factors. The most significant increase was that of the EELV program, which reported increasing its expected launches, the program's measure of quantity, by 60 resulting in an estimated $28 billion procurement cost increase, $6 billion of which was not attributable to the quantity increase.

5. **As measured against metrics discussed by GAO, the Office of Management and Budget (OMB), and DOD in 2008, only 55 percent of programs in the 2013 portfolio meet the metric for less than 10 percent cost growth over 5 years and 44 percent meet the metric for less than 15 percent growth since full first estimates; both proportions are smaller than in the 2012 portfolio, which demonstrates that a program can experience an interval of cost stability between periodic cost increases.** In December 2008, DOD, OMB, and GAO, discussed a set of outcome metrics and goals to measure program cost performance over time. The metrics are intended to measure total program cost-performance on a percentage basis over three time periods: the preceding year, the preceding 5 years, and the period since first full program estimates were

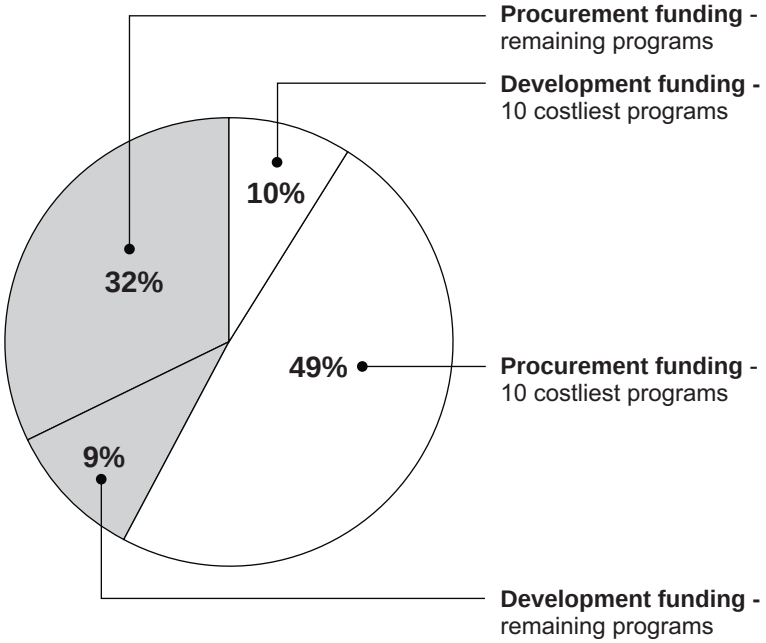
4054 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

established. We have reported on these outcomes in past assessments. Seventy-six percent of the programs in the 2013 portfolio are meeting the one-year cost performance metric by limiting their total acquisition cost growth to less than 2 percent, consistent with the cost decreases and increases explained earlier. Fewer programs, however, are meeting the metrics for limited growth in the past five years and since first full estimates; 55 percent meet the 5-year metric while 44 percent are meeting the since first full estimate metric. This demonstrates that some programs with reduced or stable costs over the past year have previously had one or more cost increases. Programs do not generally experience cost change in a linear fashion with set amounts of increase or decrease every year, rather they have periods of more dramatic change interspersed with periods of stability. The performance of the 2013 portfolio, as well as the two previous weapon system portfolios, against these metrics is shown in figure 3.

Figure 3: Comparison of the Cost Performance of DOD's 2011, 2012, and 2013 Portfolios

Source: GAO analysis of DOD data.

4055 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING



Note: Cost growth metric is defined as the percentage change in total program acquisition cost. Analysis includes the evaluation of cost growth on individual programs in the portfolio for each year. For programs where cost growth is measured on separate program sub-element, the elements were combined to calculate the cost growth on the entire program as a whole.

As a whole, aggregate cost performance of the 2013 portfolio has degraded across all three metrics from that observed in the 2012 portfolio. The percentage increase from 2012 to 2013 in programs that do not meet the cost metrics is attributable to two factors. First, many of the 12 programs that are no longer in the portfolio were meeting one or more of the three cost metrics while 2 of the 7 that entered—EELV and G/ATOR—do not meet one or more metrics. Second, performance against the cost metrics has grown worse on some of the ongoing programs. For example, the number of programs that do not meet the 1-year cost growth metric increased by 5—eight programs improved to meet this criterion in 2013 while the cost performance on 13 other programs worsened over the past year. Despite decreases in this metric in the past year, the portfolio's performance for 2013 is an improvement on the 2011 portfolio, the first year we used this metric.

6. **The 10 highest-cost programs account for 59 percent of the development and procurement cost and the majority of cost growth.** As we have reported in past assessments, the total acquisition cost of the portfolio is driven in large part by the 10 costliest programs, which currently represent 59 percent of the portfolio's development and procurement cost as shown in figure 4 below.

4056 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Figure 4: Proportion of Development and Procurement Funding for the 10 Costliest Programs

Source: GAO analysis of DOD data.

Interestingly, 6 of the 10 costliest programs in the current portfolio were also in the list of 10 costliest programs in the 2004 portfolio, and if each of these programs had executed according to the baseline approved at development start, 3 of them would have completed acquisition and exited the portfolio.

Over the past year, the 10 costliest programs incurred a net cost increase of approximately $15.4 billion, due primarily to quantity increases on the EELV program. In contrast, the other 70 programs reported a combined cost decrease of $2.8 billion. Similarly, the 10 costliest programs also account for almost 60 percent of all cost growth—or $124.4 billion—over the past 5 years in the current portfolio. Table 4 identifies the 10 costliest programs and lists their total acquisition cost and cost growth in the past year.

4057 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Table 4: Cost Changes in DOD's 10 Costliest Programs in Comparison to the Rest of the Current Portfolio

Fiscal Year 2014 dollars in billions

Program name	Current total estimated acquisition cost	Change in acquisition cost over the past year
F-35 Joint Strike Fighter	$332.3	-$11.5
DDG 51 *Arleigh Burke* Class Destroyer	107.8	2.4
Virginia Class Submarine	84.4	-2.3
Evolved Expendable Launch Vehicle	63.9	28.1
V-22 Osprey	60.7	0.8

P-8A Poseidon	34.3	-0.04
10 costliest programs	**$880.0**	**$15.4**
Total for rest of the current portfolio	**$635.2**	**-$2.8**
2013 portfolio total	**$1,515.2**	**$12.6**

Source: GAO analysis of DOD data.

Note: Some numbers may not sum due to rounding.

7. **The majority of the cost of the portfolio is concentrated in two system types and the amount and type of cost growth from first full estimate, as well as the schedule delay, varied significantly by system type.** Over 60 percent of the current portfolio's cost is accounted for by two system types—fixed wing manned aircraft and shipbuilding programs, both of which experienced unfavorable cost and schedule growth from first full estimates. The amount of cost growth, and whether that growth occurred in development or procurement, varied by the type of system acquired. Table 5 shows the amount of cost growth for development and acquisition unit cost experienced by each system type as well as the amount of schedule growth.

4058 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Table 5: Cost and Schedule Change since First Full Estimates by System Type

System type	Total development cost percentage increase	Procurement unit cost percentage increase	Percentage increase in time to deliver initial capabilities
Shipbuilding	113%	19%	53%
Unmanned vehicle	86	22	58
Rotary wing	78	74	30
Satellite	55	85	93
Fixed wing	43	55	34
C4ISR	42	-8	26
Munition	17	-10	16
Missile	13	79	30
Ground	5	62	19

Source: GAO analysis of DOD data.

Note: The procurement unit cost growth estimate was calculated using a weighted average based each program's current procurement cost that gives more expensive programs a greater value. Three of the 80 programs in the current portfolio—Chemical Demilitarization-Assembled Chemical Weapons Alternatives, EELV, and Ship to Shore Connector—were not assessed here as they do not correspond with any of the nine system types used.

The development cost growth for shipbuilding programs is the greatest among all system types and, at approximately 113 percent, is more than double that experienced by the portfolio as a whole. For example, the DDG 1000 and LCS have experienced more than 342 percent and 148 percent growth, respectively, in development costs from first full estimates. Shipbuilding programs have also experienced significant schedule delays with four out of seven programs reporting delays to the delivery of initial capability of 2 years or more. We have an extensive body of work that covers the problems DOD has experienced in developing these systems.[6]

[6]GAO, *Navy Shipbuilding: Significant Investments in the Littoral Combat Ship Continue Amid Substantial Unknowns about Capabilities,* GAO-13-530 (Washington, D.C.: July 22, 2013); *Ford-Class Carriers: Lead Ship Testing and Reliability Shortfalls Will Limit Initial Fleet Capabilities*, GAO-13-396 (Washington, D.C.: Sept. 5, 2013); *Arleigh Burke Destroyers: Additional Analysis and Oversight Required to Support the Navy's Future Surface Combatant Plans*, GAO-12-113 (Washington, D.C.: Jan. 24, 2012); *Best Practices: High Levels of Knowledge at Key Points Differentiate Commercial Shipbuilding from Navy Shipbuilding*, GAO-09-322 (Washington, D.C.: May 13, 2009); and *Defense Acquisitions: Cost to Deliver Zumwalt-Class Destroyers Likely to Exceed Budgets*, GAO-08-804 (Washington, D.C.: July. 31, 2008).

4059 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Rotary wing systems have also experienced exceptionally high levels of development cost change, with 4 out of 9 rotary wing programs experiencing more than 150 percent growth. Rotary wing programs have also experienced high amounts of growth in procurement unit cost. As an example, both the H-1 Upgrades and CH-47F Improved Cargo Helicopter have each experienced more than 150 percent growth in their average procurement unit cost since first full estimates. Satellite programs show above average growth in development cost, procurement unit cost, and schedule growth since first full estimates when compared to the portfolio as a whole. For example, Wideband Global SATCOM and Space Based Infrared System (SIBRS) High, have each experienced more than 100 percent growth in their development costs while another satellite program, the Advanced Extremely High Frequency (AEHF) Satellite, has experienced almost 200 percent growth in its average procurement unit cost. Three satellite programs have also experienced schedule growth well above the portfolio average of 36 percent with each of them reporting delays of 4 years or more. Unmanned vehicles have also experienced greater than average schedule delays with three of six unmanned vehicle programs reporting delays of 3 years or more.

8. **DOD has already been appropriated more than $833 billion for the current portfolio, leaving approximately $682 billion in costs to be funded, mostly for procurement. Approximately 45 percent of the remaining cost represents growth from first full estimates. Almost two-thirds of the future funding is needed for 10 programs, with 35 percent of the total costs remaining required for the F-35 program alone.** A larger share of the current portfolio's cost is now appropriated than had been appropriated for the portfolios from 10 or even 5 years ago. Fifty-five percent of the costs for the 2013 portfolio have already been appropriated, more than $200 billion more than in the 2004 portfolio. Forty-five percent of the total cost of the current portfolio—or $682 billion—has not yet been funded and almost 94 percent of the remaining funding—or $638 billion—is needed for procurement.

   Approximately 45 percent—or $311.6 billion—of that future funding is needed to cover cost growth from first full estimates for programs in the current portfolio. These funds represent resources that will not be available to support other defense or government priorities. We recognize that for some programs a portion of this cost growth from first full estimates may be attributable to a quantity increase. For

4060 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

example, the $14 billion in future funding needed for the DDG 51 *Arleigh Burke* Class Guided Missile Destroyer (DDG 51) is a result of quantity increases and the program has realized a significant decrease in its average procurement unit cost from first full estimates. However, in our assessments since 2011 we have found that a substantial amount of the change in the portfolio's total procurement cost could be attributable to factors other than quantity change such as production problems, inefficiencies, or flawed initial cost estimates. For example, the F-35 program requires $107 billion in future funding to cover cost growth, even though it will procure 409 fewer aircraft than originally planned. Two-thirds of all remaining funding—or $463 billion—is required by the 10 programs with the highest future funding needs and F-35 alone requires about one-third of all funding to go. The other 70 programs have only $218.8 billion in costs remaining, less than the amount of future funding needed for the F-35 program. Table 6 shows the amount of future funding needed as well as how much of that funding represents cost growth from first full estimates.

Table 6: Future Funding and Future Funding Required Due to Cost Growth from First Full Estimates

Fiscal year 2014 dollars in billions

Program name	Future funding required	Amount of future funding due to cost growth from first full estimates
F-35 Joint Strike Fighter	$239.6	$107.0
Evolved Expendable Launch Vehicle	42.9	38.4
KC-46 Tanker	40.8	0
Virginia Class Submarine	28.2	16.2
Joint Light Tactical Vehicle	23.0	0
CH-53K Super Stallion	20.7	7.4
Littoral Combat Ship	19.6	19.6
CVN 78 *Gerald R. Ford* Class Aircraft Carrier	17.5	0
P-8A Poseidon	16.8	1.7
DDG 51 *Arleigh Burke* Class Destroyer	14.0	14.0
10 programs with the largest future funding requirements	**$463.2**	**$204.3**
Totals for rest of portfolio	**$218.8**	**$107.3**
2013 portfolio total	**$682.0**	**$311.6**

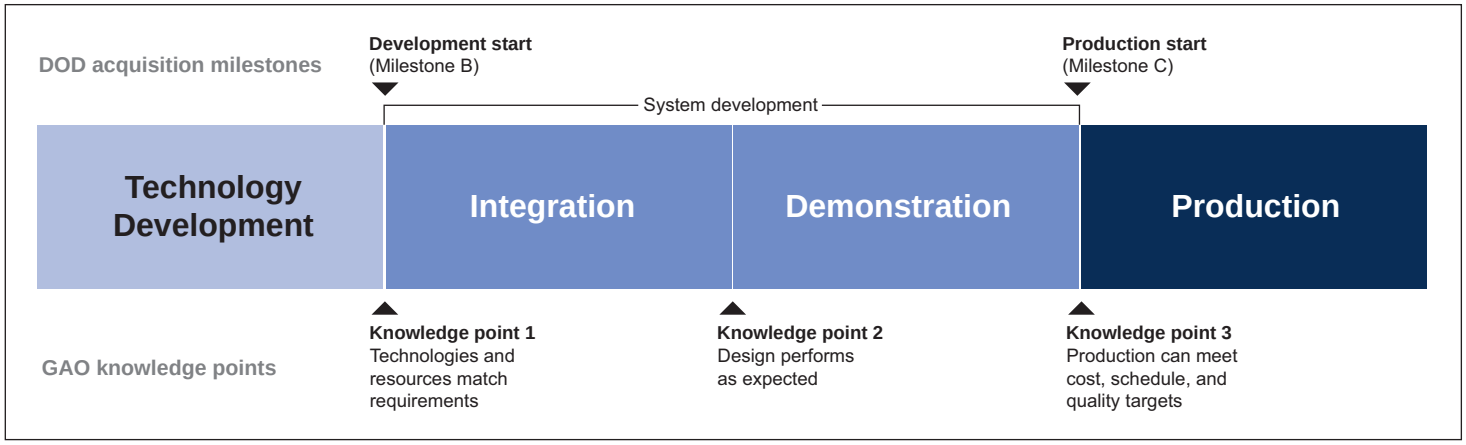
Notes: Future funding is measured as all fiscal year 2014 funding to completion of procurement. Some numbers may not sum due to rounding.

Observations from Our Assessment of Knowledge Attained by Programs at Key Acquisition Junctures

Our 2014 assessment shows that DOD continues to show progress in following a knowledge-based approach to reduce risk; however, it has significant room for improvement. While programs that have recently passed through major decision points have demonstrated best practices—such as constraining development times and achieving design stability—key practices like demonstrating technology maturity or controlling manufacturing processes are still not being fully implemented. As a result, many programs will carry risk into subsequent phases of acquisition that could result in cost growth or schedule delays.



Positive acquisition outcomes require the use of a knowledge-based approach to product development that demonstrates high levels of knowledge before significant commitments are made. In essence, knowledge supplants risk over time. In our past work examining weapon acquisition and best practices for product development, we have found that leading commercial firms and successful DOD programs pursue an acquisition approach that is anchored in knowledge, whereby high levels of product knowledge are demonstrated at critical points in the acquisition process. This work led to multiple recommendations that DOD generally or partially agreed with and has made progress in implementing.[7] On the basis of this work, we have identified three key knowledge points during the acquisition cycle—development start, the system-level critical design review, and production start—at which programs need to demonstrate critical levels of knowledge to proceed. Figure 5 aligns the acquisition milestones described in DOD's primary acquisition policy with these knowledge points. In this report, we refer to DOD's engineering and

[7]GAO, *Best Practices: Better Management of Technology Development Can Improve Weapon System Outcomes*, GAO/NSIAD-99-162 (Washington, D.C.: July 30, 1999); *Best Practices: Better Matching of Needs and Resources Will Lead to Better Weapon System Outcomes*, GAO-01-288 (Washington, D.C.: Mar. 8, 2001); *Best Practices: Capturing Design and Manufacturing Knowledge Early Improves Acquisition Outcomes*, GAO-02-701 (Washington, D.C.: July 15, 2002); *Defense Acquisitions: A Knowledge-Based Funding Approach Could Improve Major Weapon System Program Outcomes*, GAO-08-619 (Washington, D.C.: July 2, 2008); *Best Practices: High Levels of Knowledge at Key Points Differentiate Commercial Shipbuilding from Navy Shipbuilding*, GAO-09-322 (Washington, D.C.: May 13, 2009); and *Best Practices: DOD Can Achieve Better Outcomes by Standardizing the Way Manufacturing Risks Are Managed*, GAO-10-439 (Washington, D.C: Apr. 22, 2010).

4062 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

manufacturing development phase as system development. Production start typically refers to a program's entry into low-rate initial production.

Figure 5: DOD's Acquisition Cycle and GAO Knowledge Points

Source: GAO.

The building of knowledge consists of information that should be gathered at these three critical points over the course of a program:

Knowledge point 1: Resources and requirements match. Achieving a high level of technology maturity by the start of system development is one of several important indicators of whether this match has been made. This means that the technologies needed to meet essential product requirements have been demonstrated to work in their intended environment. In addition, the developer should complete a series of systems engineering reviews culminating in a preliminary design of the product that shows the design is feasible. Constraining the development phase of a program to 5 to 6 years is also recommended because it aligns with DOD's budget planning process and fosters the negotiation of trade-offs in requirements and technologies. For shipbuilding programs, critical technologies should be matured into actual system prototypes and successfully demonstrated in a realistic environment before a contract is awarded for detail design of a new ship.

Knowledge point 2: Product design is stable. This point occurs when a program determines that a product's design will meet customer requirements, as well as cost, schedule, and reliability targets. A best

4063 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

practice is to achieve design stability at the system-level critical design review, usually held midway through system development. Completion of at least 90 percent of engineering drawings at this point provides tangible evidence that the product's design is stable, and a prototype demonstration shows that the design is capable of meeting performance requirements. Shipbuilding programs should demonstrate design stability by completing 100 percent of the basic and functional drawings as well as the three-dimensional product model by the start of construction for a new ship. Programs can also improve the stability of their design by conducting reliability growth testing and completing failure modes and effects analyses so fixes can be incorporated before production begins. At this point, programs should also begin preparing for production by identifying manufacturing risks, key product characteristics, and critical manufacturing processes.

Knowledge point 3: Manufacturing processes are mature. This point is achieved when it has been demonstrated that the developer can manufacture the product within cost, schedule, and quality targets. A best practice is to ensure that all critical manufacturing processes are in statistical control—that is, they are repeatable, sustainable, and capable of consistently producing parts within the product's quality tolerances and standards—at the start of production. Demonstrating critical processes on a pilot production line is an important initial step in this effort. In addition, production and postproduction costs are minimized when a fully integrated, capable prototype is demonstrated to show that the system will work as intended in a reliable manner before committing to production. We did not assess shipbuilding programs for this knowledge point due to differences in the production processes used to build ships.

Knowledge in these three areas builds over time. A knowledge deficit early in a program can cascade through design and production leaving decision makers with less knowledge to support decisions about when and how best to move into subsequent acquisition phases that commit more budgetary resources. Demonstrating technology maturity is a prerequisite for moving forward into system development, during which the focus should be on design and integration. A stable and mature design is likewise a prerequisite for moving forward into production where the focus should be on efficient manufacturing. Additional details about key practices at each of the knowledge points can be found in appendix IV.

For this report, we assessed the knowledge attained by key junctures in the acquisition process for 38 current weapon programs, which are mostly

4064 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

in development or early production.[8] Not all programs included in our review of knowledge-based practices provided information for every knowledge point or had reached all of the knowledge points—development start, design review, and production start—at the time of this review.

Our analysis of data from these 38 major defense acquisition programs allows us to make three observations.

Knowledge Point Observations

1. The two programs that began system development in 2013—F-22 Increment 3.2B and Air and Missile Defense Radar—did not demonstrate all their critical technologies in a realistic environment and one of the two did not complete all relevant systems engineering reviews as it failed to hold a preliminary design review prior to system development. Both programs, however, intend to constrain their development phase to 6 years or less. This is consistent with the majority of the portfolio. Of the other programs we assessed, only 4 matured their technologies and 8 completed preliminary design review in time for system development, but 19 planned for a constrained development phase.

2. Of the three programs that held critical design reviews in 2013—KC-46 Tanker, Joint Light Tactical Vehicle, and Warfighter Information Network-Tactical Increment 3—two demonstrated design stability by releasing 90 percent of planned engineering drawings and all three satisfied some of the best practices related to preparation for production; but none tested an early system-level integrated prototype or demonstrated all program critical technologies in a realistic environment prior to design review. For the other programs we assessed that reported information on this review, only 6 fully matured their designs and 3 tested system-level prototypes by the time this review was held. Significant numbers had conducted activities to plan for production.

3. The two programs that held production decisions since our last assessment—Paladin Integrated Management and Ground/Air Task Oriented Radar—reported mature technologies and stable designs. Only one demonstrated performance through the testing of a production-representative prototype. Consistent with our prior assessments, neither program has demonstrated that all their critical manufacturing processes are in statistical control, and only one program used a pilot production line before beginning production. Few of the other programs in our assessment that held production decisions implemented these practices; 3 had critical processes in control and 6 had used a pilot production line.

Additional detail about these observations follows.

[8]Because knowledge points and best practices differ for shipbuilding programs, we exclude the five shipbuilding programs from some of our analysis at each of the three knowledge points.

4065 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

1. **The two programs that began system development in 2013 completed two systems engineering reviews before beginning development and plan to constrain their development phase, but one program did not carry out a preliminary design review, and neither demonstrated all its critical technologies in a realistic environment.** Both the F-22 Increment 3.2B and the Air and Missile Defense Radar (AMDR) programs entered system development with critical technologies nearing maturity—that is, demonstrated in a relevant environment—in accordance with DOD policy and statutory requirements.[9] Knowledge-based acquisition practices, however, recommend that programs fully mature technologies and demonstrate them in a realistic or operational environment prior to entering system development. Achieving this higher level of technology maturity is a better indicator of whether a program has achieved a resource and requirements match with the attainment of additional knowledge about the technologies' form, fit, and function, as well as the effect of the intended environment on those technologies.[10] Neither the F-22 Increment 3.2B nor the AMDR programs satisfied this best practice and the lower maturity level attained by these programs is consistent with our observations in past assessments on programs entering system development. Figure 6 shows the extent to which recommended acquisition practices for knowledge point 1 have been implemented on F-22 Increment 3.2B and AMDR as well as the other 36 programs we assessed.

[9]According to DOD policy at the time of our questionnaire, technology should be demonstrated in a relevant environment or, preferably, in an operational environment. In addition, a major defense acquisition program generally may not receive approval for development start until the milestone decision authority certifies that the technology in the program has been demonstrated in a relevant environment. 10 U.S.C. § 2366b(a)(3)(D).

[10]Demonstration in a relevant environment is Technology Readiness Level (TRL) 6. Demonstration in a realistic environment is TRL 7. See app. V for detailed description of TRLs.

Source: GAO analysis of DOD data.

Of the remaining 36 current programs we assessed, only 4—Excalibur Precision 155mm Projectiles (Increment 1b), Global Positioning System III, LHA 6 *America* Class Amphibious Assault Ship, and Ship-to-Shore Connector—reported that all their critical technologies were matured to best practice standards when they began development.[11] Another 11 programs we assessed reported having all critical technologies nearing maturity prior to system development. The remaining 21 programs reported either having one or more immature technologies at the start of development or reported no information on technology maturity at this critical point in the acquisition process. Of

[11]The MQ-9 Reaper program also reported all critical technologies as fully mature at development start. However, that technology assessment reflects the Reaper Block 5 configuration and not the original program. Our historical data shows that the Reaper program began development in 2004 with its technologies nearing maturity.

4067 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

the 15 programs that had reported their critical technologies as at least nearing maturity at development start, 9 have thus far constrained research and development cost growth to 15 percent or less since first full estimate. In contrast, for the 11 programs reporting one or more immature critical technologies at development start, only 2 successfully constrained research and development cost growth to 15 percent or less since their first full estimate.

Knowledge-based acquisition best practices recommend and statute requires that programs hold systems engineering events, such as a preliminary design review, before the start of development to ensure that requirements are defined and feasible and that the proposed design can meet those requirements within cost, schedule, and other system constraints. The Weapon Systems Acquisition Reform Act of 2009 (WSARA) made it a statutory requirement that major defense acquisition programs generally hold a preliminary design review before the start of system development.[12] According to the program offices, the F-22 Increment 3.2B program conducted a preliminary design review prior to entering system development, but the AMDR program did not, and instead sought and received a waiver to this requirement. Currently, AMDR plans to conduct a preliminary design review in June 2014. Of the remaining 36 current programs we assessed, only 8 held a preliminary design review prior to development start, including 4 programs that began development start before 2009, and another 4 programs that started development after implementation of WSARA. Our analysis of the current portfolio shows that programs that conducted a preliminary design review prior to development start have, on average, experienced a lower rate of research and development cost growth and a lower rate of total acquisition cost growth, compared with programs that did not have a preliminary design review before development start. Of the eight assessed programs that held this review prior to development start, six have thus far constrained research and development cost growth to less than 15 percent since first full estimate. Of the 22 assessed programs that did not carry out a

[12]Pub. L. No. 111-23, § 205(a). A major defense acquisition program may not receive milestone B approval until the program has held a preliminary design review and the milestone decision authority has conducted a formal post-preliminary design review assessment and certified on the basis of such assessment that the program demonstrates a high likelihood of accomplishing its intended mission unless a waiver is properly granted by the milestone decision authority. 10 U.S.C. § 2366b(a)(2), (d)(1).

4068 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

preliminary design review prior to development start, only 8 were successful in restraining development cost growth below 15 percent.

In addition to the preliminary design review, knowledge-based acquisition best practices recommend the completion of two additional systems engineering reviews: one review to ensure that system requirements have been properly identified, which helps ensure mutual understanding between government and contractor; and a system functional review to establish a functional baseline for the system. Both the F-22 Increment 3.2B and AMDR programs completed these reviews prior to entering system development. Of the remaining 36 programs we assessed, only 10 completed both reviews prior to development start—five that entered system development before 2009 and another 5 that began system development after 2009.

Knowledge-based acquisition practices also recommend that a program constrain the development phase to just 5 or 6 years, and both the F-22 Increment 3.2B and AMDR programs plan to do so.[13] By limiting development time in this manner, a program increases the predictability of funding needs, as well as the likelihood of program success by fostering the negotiation of trade-offs in requirements and technologies.[14] For the remaining 31 non-ship programs we assessed, 19 had plans to limit their development phases to 6 years or less at the time of development start. This includes 13 out of 23 programs that began development prior to 2009 and another 6 out of 8 programs that began system development during or after 2009.

As part of our analysis, we also assessed 18 future programs that expect to become major defense acquisition programs. These programs provided information on the knowledge they planned to obtain and best practices they intend to implement before their development start is approved. Seven of 18 future programs reported

[13]We did not assess shipbuilding programs against this recommended practice to limit the development phase, as their development cycles do not align in a manner consistent with other programs.

[14]DOD policy in place at the time of our review provided that a condition for exiting the technology development phase is that a system or increment be developed for production within a short time frame, defined as normally less than 5 years for weapon systems. Department of Defense Instruction 5000.02, *Operation of the Defense Acquisition System*, enc. 2, para. 5.d(7) (Dec. 8, 2008) (hereinafter cited as DODI 5000.02 (Dec. 8, 2008). An interim version of this instruction was issued in November 2013.

4069 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

that their technologies are expected to be nearing maturity; that is demonstrated in a relevant environment, at the time of development start. Ten of the future programs plan to hold a preliminary design review before the start of development and only seven plan to conduct both a system functional and system requirements review before the start of development. Nine of the future programs reported plans to limit the program development phase to 6 years or less. If these plans continue unaltered, programs will enter system development with insufficient knowledge about their ability to meet cost, schedule, and performance requirements. The decision to proceed without this knowledge involves more than the program at hand, it sends signals across the portfolio of programs on what is acceptable. If programs that do not abide by sound acquisition principles win funding, then seeds of poor outcomes are planted. Top decision makers must ensure that new programs exhibit desirable principles before they are approved and funded; the proper time to establish that is at program start.

2. **Of the three programs that held critical design reviews in 2013, two demonstrated design stability by releasing 90 percent of expected engineering drawings, but none tested an early integrated prototype or demonstrated all critical technologies in a realistic environment prior to this design review.** Knowing a product's design is stable before system demonstration reduces the risk of costly design changes as manufacturing begins and investments in acquisition become more significant. Just as programs that enter system development with immature technologies cost more and take longer to deliver their operational capabilities to the warfighter, programs that hold their critical design review before achieving a stable design also experience higher average costs and longer schedule delays. Figure 7 presents whether the programs implemented this, as well as other, best practices.

Of the three programs that held their critical design review in 2013, both the KC-46 Tanker and the Joint Light Tactical Vehicle (JLTV) demonstrated design stability by releasing over 90 percent of each program's expected design drawings.[15] According to the Warfighter Integration Network-Tactical Increment 3 (WIN-T Inc 3) program office this practice was not applicable as the system relies primarily on

[15]According to JLTV program officials, a series of design understanding reviews were held with each of the program's three current contractors that served as the equivalent of a single critical design review. At the time of these reviews, all long-lead and critical designs had been completed and all three contractors had more than 90 percent of the design files under configuration control.

4071 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

software for its functionality.[16] Of the remaining programs we assessed, 30 reported information about the practices they implemented at their critical design review. Of these, only 6 non-ship programs released at least 90 percent of their total expected design drawings before holding this review, and no shipbuilding programs met the shipbuilding-specific best practice of completing 100 percent of their three-dimensional design models prior to the start of fabrication. All 6 of the programs with a stable design held their critical design review since 2009.

The use of early system prototypes during development is another useful practice for demonstrating that a system has a stable design, will work as intended, and can be built within cost and schedule. None of the three programs reported testing an integrated system prototype before their critical design review or its equivalent. Instead, the JLTV program reported conducting this system prototype testing 7 months after its design review, and the KC-46 Tanker program will not begin flight testing a system-level prototype that integrates the civilian aircraft and military sub-systems until January 2015, 18 months after its critical design review. WIN-T Inc 3 did not plan to test a system-level prototype until October 2015, 22 months after its critical design review. Of the 25 non-ship programs we assessed that have held a critical design review, 21 report they tested or plan to test an early integrated prototype but only 3 programs conducted this testing before their critical design review.[17] For the other 18 programs, prototype testing followed the review by an average of nearly 3 years (or 33 months). This use of early system prototypes among programs we assessed is much the same as past assessments.

Reliability growth testing provides visibility over how reliability is improving and uncovers design problems so fixes can be incorporated before production begins. All three programs reported establishing a reliability growth curve by their critical design review. Of the remaining

[16]While the WIN-T Inc 3 program held a critical design review in December of 2013 that assessed the entirety of the developmental program, it later had its requirements and capabilities reduced through descoping options recommended at a configuration steering board review and approved by the Army acquisition executive in January 2014.

[17]We did not assess the five shipbuilding programs against this recommended practice as testing early system prototypes in these programs may not be practical.

4072 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

30 programs we assessed that have held critical design review, or its equivalent, 14 had a reliability growth curve at that time.

The programs we assessed also reported use of other knowledge-based practices to increase confidence in the stability of their product's design. Those practices include the identifying key product characteristics; identifying critical manufacturing processes; conducting producibility assessments to identify manufacturing risks; and completing failure modes and effects analysis to identify potential failures and early design fixes. The KC-46 Tanker program carried out all four of these practices, while the JLTV program carried out three and the WIN-T Inc 3 program implemented two. For the 30 other programs we assessed with a critical design review prior to 2013, a little more than half of them reported having used all four of these practices. This rate of implementation is similar to what we observed in our prior year assessment.

3. **The two programs that held production decisions since our last assessment reported mature technologies and stable designs, and one of the two demonstrated performance through the testing of a production-representative prototype; neither demonstrated that all their manufacturing process capabilities were in control.** Capturing critical manufacturing knowledge before entering production helps ensure that a weapon system will work as intended and can be manufactured efficiently to meet cost, schedule, and quality targets. This knowledge can be captured and demonstrated through the use of various proactive methods, including the use of statistical process control data, pilot production lines, manufacturing readiness levels, and prototype testing. Figure 8 shows the extent to which programs that have held a production decision have implemented associated knowledge-based practices.

Source: GAO analysis of DOD data.

Neither the Paladin Integrated Management (PIM) program, which held a production decision in 2013, nor the G/ATOR program, which held a production decision in January 2014, demonstrated that their manufacturing process capabilities were in control at production start.[18] Of the remaining programs we assessed, 16 non-ship programs held production decisions prior to 2013, of which only 3 provided data indicating that critical manufacturing processes were in control at production start.[19] Though the PIM program did not test a pilot production line prior to production start, the G/ATOR program reported that it has. Of the 16 programs that held production decisions prior to

[18]To determine whether critical processes are in control, we used program reported process capability index data and manufacturing readiness level assessments of the process capability and control sub-thread.

[19]The five shipbuilding programs we assessed were excluded from this portion of our analysis due to the differences in the production processes used to build ships.

4074 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

2013, only 6 have demonstrated manufacturing processes on a pilot production line. Another 14 programs we assessed plan to hold a production decision in the future and only 6 indicated that they intend to test a pilot production line before production start.

Production and postproduction costs are also minimized when a fully integrated, production-representative prototype is demonstrated to show that the system will work as intended in a reliable manner. DOD policy has also required that a system be demonstrated in its intended environment using a production-representative article before entering production, which has led to an increase in the number of programs doing so.[20] The G/ATOR program has tested a production-representative prototype in its intended environment in advance of their production decision, but PIM has not. Of the 16 programs we assessed that held a production decision prior to 2013, only 6 tested production-representative prototypes prior to their production start. For the other 14 programs we assessed that plan to hold a production decision in the future, only 5 currently have plans to test a production-representative prototype before reaching this key juncture. In not testing such prototypes these programs risk repeating the experiences of the past when issues were discovered late in testing, triggering the need for expensive re-tooling of production lines and retrofitting of production articles.

Observations about DOD's Implementation of Key Acquisition Reform Initiatives and Program Concurrency

During the past few years, the Congress and DOD have made policy changes and begun other reform initiatives to improve the way the department acquires major weapon systems and address the symptoms of an acquisition system that include frequent program cost overruns and delays in operational capability delivery. More specifically, the enactment of the Weapon Systems Acquisition Reform Act of 2009, the promulgation of multiple "Better Buying Power" memorandums by the Under Secretary of Defense for Acquisition, Technology, and Logistics, and the revision of DOD Instruction 5000.02 in 2008 and interim revision in 2013, represent efforts to increase competition in weapon programs, decrease acquisition

[20]DODI 5000.02, enc. 2, para. 6.c(6)(d) (Dec. 8, 2008).

4075 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

costs, and ensure that programs are more affordable.[21] We focused our analysis on efforts within the "Better Buying Power" memorandums, particularly affordability constraints and "should-cost" analysis. These efforts attempt to control program costs by introducing, respectively, constraints on total cost and a review process to eliminate unnecessary costs from contracts. We also analyzed the implementation of two reforms addressed in legislation, the requirement to increase competition throughout the acquisition life cycle and the requirement that major defense acquisition programs hold annual configuration steering board reviews to consider changes regarding program requirements and maximize capabilities. GAO has previously made recommendations or observations on the implementation of a number of these reform initiatives and DOD, which has generally concurred or partially concurred with the recommendations, is working to implement them.[22] In addition, we evaluated the amount of concurrency between developmental testing and production for programs we assessed that have started production as well as those that plan to begin production in the coming years.[23] We have consistently emphasized the importance of completing developmental

[21]Pub. L. No. 111-23. DODI 5000.02 (Dec. 8, 2008) and Interim DODI 5000.02, *Operation of the Defense Acquisition System* (Nov. 25, 2013). As our data was collected prior to the release of the latest revision of DODI 5000.02, we did not use the new instruction as criteria for our assessments.

[22]GAO, *Weapons Acquisition Reform: Reform Act Is Helping DOD Acquisition Programs Reduce Risk, but Implementation Challenges Remain*, GAO-13-103 (Washington, D.C.: Dec. 14, 2012); *Defense Acquisitions: DOD Can Improve Its Management of Configuration Steering Boards,* GAO-11-640 (Washington, D.C.: July 7, 2011); *Defense Acquisitions: Assessments of Selected Weapon Programs*, GAO-13-294SP (Washington, D.C.: Mar. 28, 2013).

[23]This analysis reflects 30 non-ship programs out of the 38 programs we assessed and does not include three non-ship programs for which a production start date was not identified as well as five shipbuilding programs. Shipbuilding programs are excluded from this analysis as we assess production knowledge for ships differently.

4076 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

testing before entering production, and pointed out the increased risks associated with concurrent testing and production.[24]

To gain some perspectives on the implementation of key aspects of policy changes and reform initiatives within DOD's current portfolio, we analyzed questionnaire data collected from 38 current major defense acquisition programs—the same programs reflected in our knowledge point analysis—and 18 additional programs identified by DOD as future major defense acquisition programs.

Implementation of the reform initiatives we analyzed varies across programs. The department has largely been successful in implementing its "should-cost" initiative with significant cost savings being reported. In addition, many programs reported holding configuration steering board reviews. In contrast, the department has had less success in implementing affordability constraints and utilizing measures to ensure competition before and after development start—initiatives that also have the potential to result in savings. In addition, many programs are committing to production prior to completing the developmental testing necessary to assure that the system will function as intended, introducing unnecessary risk to cost and schedule. Our current analysis allows us to make the following five observations concerning key acquisition reform initiatives and program concurrency.

[24]*GAO, Joint Strike Fighter: DOD Actions Needed to Further Enhance Restructuring and Address Affordability Risks,* GAO-12-437 (Washington, D.C.: June 14, 2012); *Missile Defense: Opportunity Exists to Strengthen Acquisitions by Reducing Concurrency,* GAO-12-486 (Washington, D.C.: Apr. 20, 2012); and *Best Practices: Capturing Design and Manufacturing Knowledge Early Improves Acquisition Outcomes*, GAO-02-701 (Washington, D.C.: July 15, 2002).

4077 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Acquisition Reform and Concurrency Observations

1. Only 30 of the 56 current and future programs we assessed have established an affordability constraint, an implementation rate that has not improved from our prior year assessment, but all programs with a cap that we assessed reported they are on track to meet it.

2. About 82 percent of the current programs we assessed have conducted a "should-cost" analysis resulting in anticipated savings of approximately $24 billion; over half of this amount has or will be reallocated from these programs for other priorities.

3. Many of the future programs we assessed do not plan to conduct competitive prototyping before development start and many current programs do not have acquisition strategies that ensure competition through the end of production. Fifteen future and current programs reported they will not take actions to promote any competitive measures before or after development start.

4. All but 1 of the 38 current programs we assessed had conducted a configuration steering board review with 29 programs reporting that this review occurred during the past year. Only 10 programs reported that changes were approved or recommended at their last review.

5. Fifteen of the 18 current programs we assessed that have started production plan to perform 30 percent or more of their developmental testing during production despite the increased risk of design changes and costly retrofits. Five of these programs expect to place substantial procurement quantities under contract before developmental testing is completed.

Additional details about each observation follow.

1. **Only 30 of the 56 current and future programs we assessed have established an affordability constraint, an implementation rate that has not improved from our prior year assessment, but all programs with a cap that we assessed reported they are on track to meet it.** In September 2010, the first of several memorandums were issued by the Under Secretary of Defense for Acquisition, Technology, and Logistics directing programs to consider affordability a key program requirement and outlining how this initiative was to be

4078 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

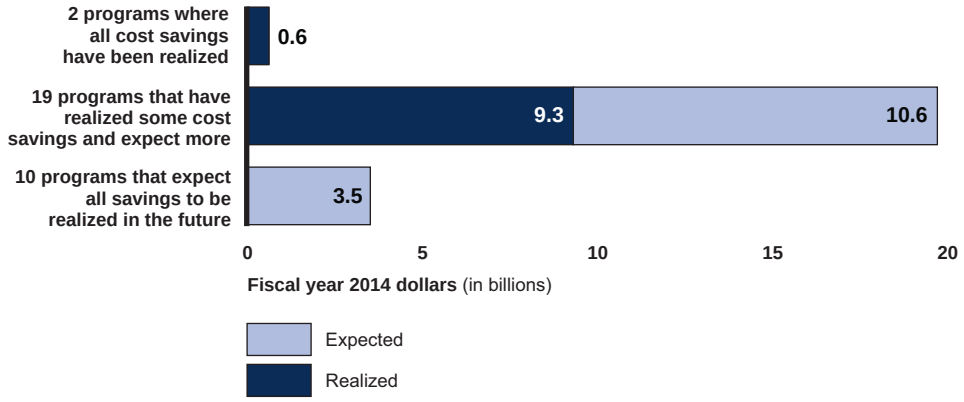
implemented across the department.[25] The memorandums emphasize the need to treat affordability, defined as conducting a program at a cost constrained by the resources that DOD can allocate, as a key requirement at the start of development. Affordability constraints are intended to force prioritization of requirements, enable cost trades and ensure that unaffordable programs do not enter the acquisition process.[26] More than half of the current and future programs (30 of 56) we assessed have established an affordability constraint as directed by the "Better Buying Power" initiatives and all these programs reported that they are on track to meet their established constraint. The rate of implementation of this reform has not improved from the level reported in our prior assessment. For the 38 current programs, 18 have not established an affordability cap and almost all of these programs are nearing a production decision or are already in production. In general, these 18 programs are older and have smaller percentages of funding remaining than those current programs with an affordability cap. Similarly, for the 18 future programs, 8 reported a lack of an established affordability goal. Two of them reported holding a milestone A review during 2013—where an affordability goal would normally be established—while a third program held its milestone A review in 2009 before the affordability requirement was established by DOD policy and the remaining 5 responded that the timeframe for this review was "to be determined" or "not applicable."

2. About 82 percent of the current programs we assessed have conducted a "should-cost" analysis resulting in anticipated

[25]Office of the Under Secretary of Defense, Acquisition, Technology, and Logistics Memorandum: "Better Buying Power: Guidance for Obtaining Greater Efficiency and Productivity in Defense Spending" (Sept. 14, 2010). Office of the Under Secretary of Defense, Acquisition, Technology, and Logistics Memorandum: "Implementation Directive for Better Buying Power - Obtaining Greater Efficiency and Productivity in Defense Spending" (Nov. 3, 2010). Office of the Under Secretary of Defense, Acquisition, Technology, and Logistics Memorandum: "Better Buying Power 2.0: Continuing the Pursuit for Greater Efficiency and Productivity in Defense Spending" (Nov. 13, 2012). Office of the Under Secretary of Defense, Acquisition, Technology, and Logistics Memorandum: "Implementation Directive on Better Buying Power 2.0: Achieving Greater Efficiency and Productivity in Defense Spending" (Apr. 24, 2013).

[26]Affordability goals are established at milestone A, the entry into technology development. After systems engineering trade-offs are completed during the technology development phase, these affordability goals then become affordability caps at milestone B, the start of system development, when a match is to be made between requirements and resources. We refer to the goals and caps collectively as affordability constraints.

4079 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING



savings of approximately $24 billion; over half of this amount has or will be pulled from these programs for other priorities. DOD's "Better Buying Power" initiatives also emphasize the importance of driving cost improvements during contract negotiation and program execution to control costs both in the short-term and throughout the product life cycle. In accordance with direction provided in memorandums issued by the Under Secretary, each program must conduct a "should-cost" analysis which includes justifying each cost under the program's control with the aim of reducing negotiated prices for contracts and obtaining other efficiencies in program execution. More broadly, "should-cost" is the concept that program managers are to proactively control expenditures by setting cost targets below what has been budgeted for their program's activities and manage with the intent to achieve these lower targets.

According to our analysis of questionnaire responses, 32 of 38 current programs we assessed conducted a "should-cost" analysis as directed by the "Better Buying Power" initiatives and 31 of the programs reported that they had realized or expect to realize cost savings totaling approximately $24 billion in fiscal year 2014 dollars as shown in figure 9 below.[27]

[27]One of the 32 programs that conducted a "should-cost" analysis—the LCS program—reported "should-cost" savings of $5.8 billion in then-year dollars, which were not comparable to the base year data we received from other programs and is not reflected in the $24 billion fiscal year 2014 constant dollar amount.

4080 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Figure 9: Realized and Expected "Should-Cost" Savings Reported by 31 Programs

Source: GAO analysis of questionnaire data.

Approximately 41 percent, $9.9 billion, of all the "should-cost" savings were identified as realized, with the other 59 percent, or $14.1 billion, expected in the future. When savings were converted into fiscal year 2014 constant dollars, 6 of the programs reported savings of more than $1 billion, the largest of which was the KC-46 Tanker program which reported a savings total of $6.8 billion with nearly $6.4 billion of this amount already realized. For the 6 current programs that reported they did not conduct a "should-cost" analysis, 3 were being restructured during our assessment after reporting an increase in cost or schedule above their acquisition program baselines, and another had recently entered system development.

The 18 programs that reported some or all of their "should-cost" savings as realized cited several activities as being responsible including

- improved vendor/supply chain management (10 programs),
- developmental or operational testing efficiencies (12 programs), and
- design trades conducted to balance affordability and capability (12 programs).

As a specific example, the DDG 51 program reported that nine different activities were carried out to obtain approximately $506 million in realized cost savings including the three activities above, while the

4081 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

JLTV program cited two activities—design trades balancing affordability and capability and changes in requirements—to achieve $206 million in realized cost savings with another $412 million in savings expected in the future. These savings may manifest themselves in the program by lower contract prices, lower program cost estimates, and possibly lower funding requests.

Achieving efficiency needs to be done with caution as the short-term savings could come at the expense of long-term needs. For example, six of the programs that reported implementing testing efficiencies for savings are also planning to conduct concurrent developmental testing and production which leaves these programs at risk to deficiencies being discovered during production that could require substantial and costly modifications to systems already built. Similarly, four programs that started production before 2011 reported that changes in design or requirements will result in some savings, but carrying out this "should-cost" activity after production start could contribute to design instability. In addition, 7 programs stated that savings are being realized from the increased use of modeling and simulation but only 3 of these programs reported that all the models being used for operational and live fire testing were officially reviewed and certified as acceptable for their intended use. While the use of models and simulations can reduce the time and resources needed to conduct the required testing, using models that are not fully accredited to meet weapons system testing objectives increases the likelihood that an inappropriate or unsuitable simulation is being used.

Of the approximately $24 billion in realized and anticipated "should-cost" savings, a total of $12.6 billion was reallocated to meet other service and DOD priorities. For example, the KC-46 Tanker program reported that all of its "should-cost" savings, totaling $6.8 billion, will be reinvested in other service and Office of the Secretary of Defense priorities. Approximately $6.3 billion was reported as retained by 16 programs we assessed. While several other programs reported that their savings, a total of $3.6 billion, were split among different activities with some amounts retained and some reallocated for other priorities. For example, the F-35 program reported that some of the $884 million in expected savings will be put to use by the program while other amounts will be reinvested in other service and Office of the Secretary of Defense priorities. An additional $1.5 billion in savings was reported as a part of our questionnaire but programs stated that they did not know or had not yet determined how these funds would be

4082 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

re-allocated. The concept of allowing programs to keep at least some of their savings is appropriate, but the department should take care to use this incentive effectively.

Of the 18 future programs that we assessed, 6 reported that they conducted a "should-cost" analysis prior to entering system development which identified approximately $26 billion in realized and expected savings. The vast majority of this amount was reported by the Ohio Replacement and Ground Combat Vehicle (GCV) programs with $16 billion and $8.5 billion, respectively, in "should-cost" savings. The Ohio Replacement program reported that all $16 billion in procurement and other savings were expected in the future and would result from several ongoing affordability initiatives including design for producibility initiatives and potentially procuring boats in a multi-year procurement block buy with *Virginia* Class submarines. In contrast, the GCV program reported all its $8.5 billion in savings as realized. The program claims savings were due to design trades to balance affordability and capability and the award of a fixed-price development contract among other activities. The decision to eliminate competition during system development and production was reported as responsible for a decrease in the program's expected cost.

3. **Many of the future programs we assessed do not plan to conduct competitive prototyping before development start and many current programs do not have acquisition strategies that ensure competition through the end of production. Fifteen future and current programs reported they will not take actions to promote any competitive measures before or after development start.** Competition is a critical tool for achieving the best return on the government's investment. Major defense acquisition programs are required to provide for the use of competitive prototypes before a program enters system development and have acquisition strategies that ensure competition or the option of competition throughout the acquisition life cycle.[28] Table 7 shows the activities programs report using or plan to use to ensure competition or the possibility of competition.

[28]Pub. L. No. 111-23, §§ 202, 203.

4083 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Table 7: Use of Activities to Ensure Competition Reported by Future and Current Programs

Activity to ensure competition is utilized[a]		Of the 18 future programs	Of the 38 current programs
Competitive prototyping prior to development start	Competitive prototyping planned or conducted	9	16
	No competitive prototyping planned or conducted	8	22
Measures to ensure competition after development start included in program strategy[b]	Measures to ensure competition are planned or have taken place	8	21
	No measures included	8	17
	Actions taken to promote competition both prior to and after development start	5	10
	No actions taken to promote competition	4	11

Source: GAO analysis of questionnaire data.

[a]One future program—the Amphibious Combat Vehicle—was not included in the totals above for competitive prototyping as it did not know whether such a competition would be conducted prior to development start. Two future programs—the Amphibious Combat Vehicle and Indirect Fire Protection Capability Increment 2—were not counted in the totals for measures to ensure competition as they both did not know whether their technology development or acquisition strategies would call for competition between development start and the completion of production.

[b]We use program strategy to refer to both technology development strategies used by future programs and the acquisition strategies used by current programs.

Only 25 of 56 current and future programs we assessed reported conducting or planning for any form of competitive prototyping prior to the start of system development. Of the 22 current programs with no competitive prototyping, only 2 reported that the requirement was waived pursuant to DOD policy implementing WSARA. The other 20 programs that reported the competitive prototyping requirement was not waived either began development before December 2009, when WSARA was implemented, or proceeded directly to production. The future programs we assessed reported that they plan to conduct competitive prototyping at a slightly higher rate than the current programs we assessed. However, 8 future programs still reported that they do not intend to conduct competitive prototyping. Of these, 7 plan to seek a waiver to this requirement with the remaining one reporting that the requirement to seek a waiver was not applicable.

Measures in a program's acquisition strategy to ensure competition or the option of competition after a program enters system development may include approaches such as the use of modular, open architectures to enable competition for upgrades or the use of build-to-print approaches to enable production through multiple

4084 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

sources.[29] But as shown in table 7 above, only 29 of 56 current and future programs reported that their acquisition strategies currently include measures to ensure competition after the start of development. Twenty-six of these programs stated that some or all of their activities to promote competition will take place in the future.

Overall, only 10 current programs and 5 future programs have taken or plan to take actions to promote competition both before and after the start of the development. In contrast, 11 current programs and 4 future programs reported that they have not taken any actions, nor do they plan to take any, to ensure competition or the option of competition for acquisition at any point after program initiation. This does not mean that these programs will have no competition at any point during their acquisition; only that they do not intend to ensure competition through the specific activities we assessed.

4. **All but one of the 38 current programs we assessed had conducted a configuration steering board (CSB) review, 29 reported that this review occurred during the past year. Only 10 programs reported that proposed changes were approved or recommended at the most recent review.** According to statute and DOD's acquisition policy at the time of our review, major defense acquisition programs are required to conduct annual configuration steering boards to review proposed changes to the program's requirements or significant technical configuration changes that may impact cost and schedule performance.[30] Thirty-seven current programs we assessed had conducted such a review. The Air and Missile Defense Radar program was the only exception, as it just started development in October 2013 and was not required to complete the review by the time of our assessment. A majority, 29 out of 37 programs, reported that this review occurred in the 12 months prior to the submission of our questionnaire.

[29]Open systems architecture is a design approach that includes standard interfaces and the use of modular components within a product (like a computer) that can be replaced easily. This allows the product to be refreshed with new, improved components made by a variety of suppliers.

[30]Duncan Hunter National Defense Authorization Act for Fiscal Year 2009, Pub. L. No. 110-417, § 814 (2008).

4085 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Only 12 of the current programs we assessed reported presenting any changes at their last CSB review. Of these, 10 programs had proposed requirements changes, configuration changes, descoping options, or some combination of these, which they reported were approved or recommended for approval. For example, the DDG 1000 *Zumwalt* Class Destroyer program reported that both configuration changes and descoping options were approved or recommended for approval at their June 2012 review, while the F-35 program reported that requirements changes were approved or recommended at their March 2013 review. However, some changes to capabilities have occurred outside of the CSB process. For the 38 current programs we assessed, 14 reported that planned system capabilities have either increased or decreased since the start of development. Only 5 of these programs indicated that a CSB review was one of the contributing reasons for the change. Many of these 14 programs reported that requirements changes since development start have caused cost and schedule changes as well.

5. **Fifteen of the 18 current programs we assessed that have started production plan to perform 30 percent or more of their developmental testing during production despite the increased risk of design changes and costly retrofits. Five of these programs expect to place substantial procurement quantities under contract before developmental testing is completed.** Beginning production before demonstrating that a design is mature and that a system will work as intended increases the risk of discovering deficiencies during production that could require substantial design changes and costly modifications to systems already built. The intent of developmental testing is to demonstrate the maturity of a design and to discover and fix design and performance problems before a system enters production. However, 15 out of the 18 programs we assessed that have started production intend to or have already executed 30 percent or more of their developmental testing concurrent with production. Seven of these 15 programs have completed developmental testing with 4 of them reporting quality problems during production.

   Five of the other 8 programs currently conducting concurrent testing and production, expect to have more than 10 percent of their procurement quantities under contract before developmental testing completes. The F-35 program in particular plans to have 530 aircraft, more than 20 percent of its total procurement quantity, under contract

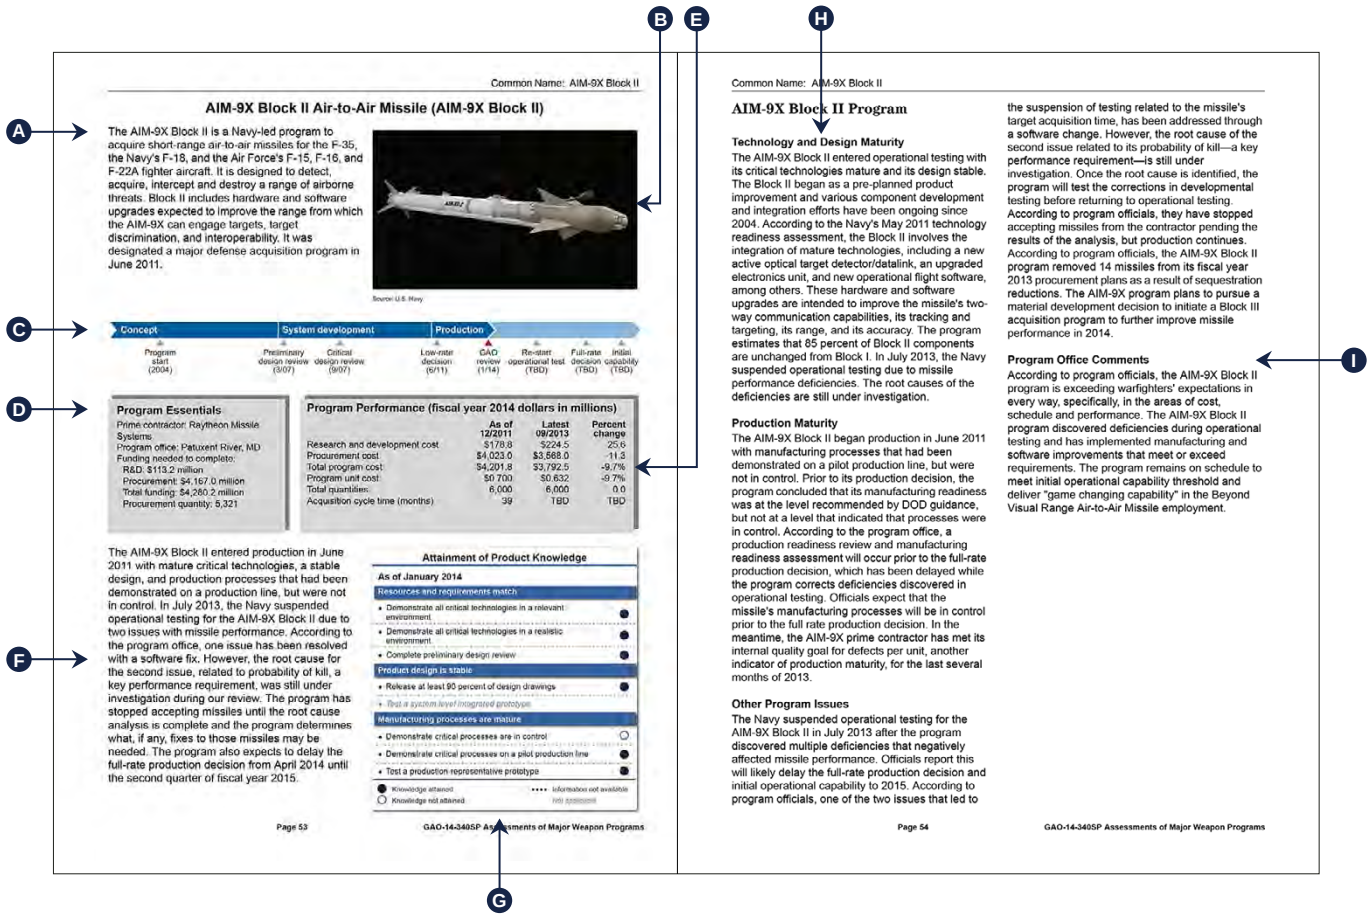
4086 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

at a cost of approximately $57.8 billion before developmental testing is completed in 2017.[31] When considering the point at which budgets to support those procurements are typically approved—up to 18 months in advance—it places the commitment of funding that much further ahead of the completion of developmental testing.

Another twelve programs we assessed are scheduled to make a production decision in the coming years and 6 of them intend to execute 30 percent or more of their developmental testing concurrent with production. Two out of these six programs expect to have more than 10 percent of their total procurement quantity under contract before developmental testing is finished running the risk of costly retrofits to existing systems or changes to active production lines.

Assessments of Individual Programs

This section contains assessments of individual weapon programs. Each assessment presents data on the extent to which programs are following a knowledge-based acquisition approach to product development, and other program information. In total, we present information on 56 programs. For 37 programs, we produced two-page assessments discussing the technology, design, and manufacturing knowledge obtained, as well as other program issues. Each two-page assessment also contains a comparison of total acquisition cost from the first full estimate for the program to the current estimate. The first full estimate is generally the cost estimate established at development start; however, for a few programs that did not have such an estimate, we used the estimate at production start instead. For shipbuilding programs, we used their planning estimates if those estimates were available. For programs that began as non–major defense acquisition programs, we used the first full estimate available. Thirty-four of these 37 two-page assessments are of major defense acquisition programs, most of which are in development or early production and 3 assessments are of programs that were projected to become major defense acquisition programs during or soon after our review. See figure 10 for an illustration of the layout of each two-page assessment. In addition, we produced one-page assessments on the



[31]The cost of the F-35 aircraft under contract before the completion of developmental testing was calculated using the average procurement unit cost for both the airframe and engine as reported in the program's December 2012 Selected Acquisition Report. This unit cost estimate assumes the quantity benefits from additional purchases of F-35 aircraft by international partners and other foreign military sales.

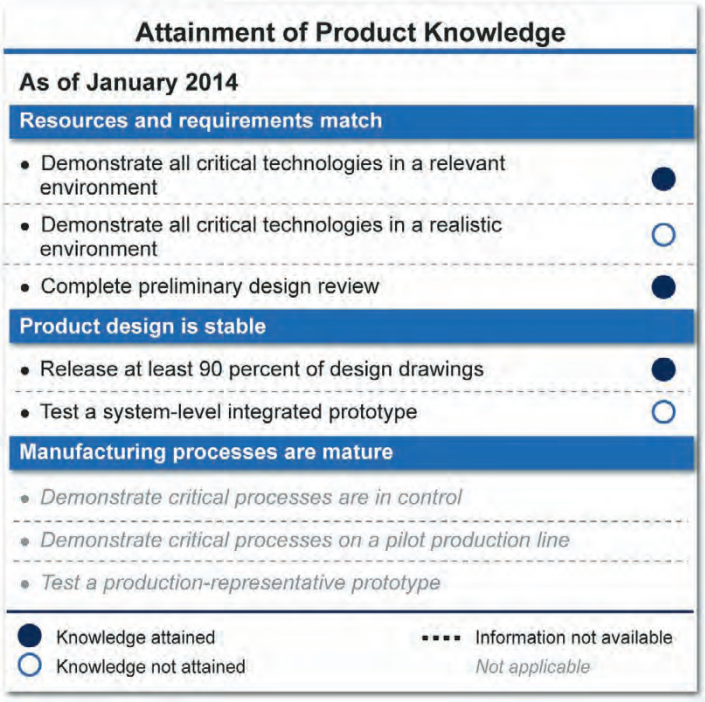
4089 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

For our two-page assessments, we depict the extent of knowledge gained in a program by the time of our review with a scorecard and narrative summary at the bottom of the first page of each assessment. As illustrated in figure 10 above, the scorecard displays eight key knowledge-based acquisition practices that should be implemented by certain points in the acquisition process. The more knowledge the program has attained by each of these key points, the more likely the weapon system will be delivered within its estimated cost and schedule. A knowledge deficit means the program is proceeding without sufficient knowledge about its technologies, design, or manufacturing processes, and faces unresolved risks that could lead to cost increases and schedule delays.



For each program, we identify a knowledge-based practice that has been implemented with a closed circle. We identify a knowledge-based practice that has not yet been implemented with an open circle. If the program did not provide us with enough information to make a determination, we show this with a dashed line. A knowledge-based practice that is not applicable to the program is grayed out. A knowledge-based practice may not be applicable to a particular program if either the point in the acquisition cycle when the practice should be implemented has not yet been reached, or if the particular practice is not relevant to the program. For programs that have not yet entered system development, we show a projection of knowledge attained for the first three practices. For programs that have entered system development but not yet held a critical design review, we assess actual knowledge attained for these three practices. For programs that have held a critical design review but not yet entered production, we assess knowledge attained for the first five practices. For programs that have entered production, we assess knowledge attained for all eight practices.

We make adjustments to both the key points in the acquisition cycle and the applicable knowledge-based practices for shipbuilding programs. For shipbuilding programs that have not yet awarded a detailed design contract, we show a projection of knowledge attained for the first three practices. For shipbuilding programs that have awarded this contract but not yet started construction, we would assess actual knowledge attained for these three practices. For shipbuilding programs that have started construction, we assess the knowledge attained for the first four practices. We do not assess the remaining four practices for shipbuilding programs. See figure 11 for examples of the knowledge scorecards we use to assess these different types of programs.

Statement on Small Business Participation

Pursuant to a mandate in the report accompanying the National Defense Authorization Act for Fiscal Year 2013, we reviewed whether individual subcontracting reports from a program's prime contractor or contractors were accepted on the Electronic Subcontracting Reporting System (eSRS).[32] We reviewed this information for 36 of the major defense acquisition programs in our assessment using the contract information reported in available Selected Acquisition Reports. The contract numbers for each program's or element's prime contracts were entered into the eSRS database to determine whether the individual subcontracting reports from the prime contractors had been accepted by the government. The government uses individual subcontracting reports on eSRS as one

[32]H.R. Rep. No. 112-479, at 284 (2012), *accompanying* Pub. L. No.112-239

4091 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

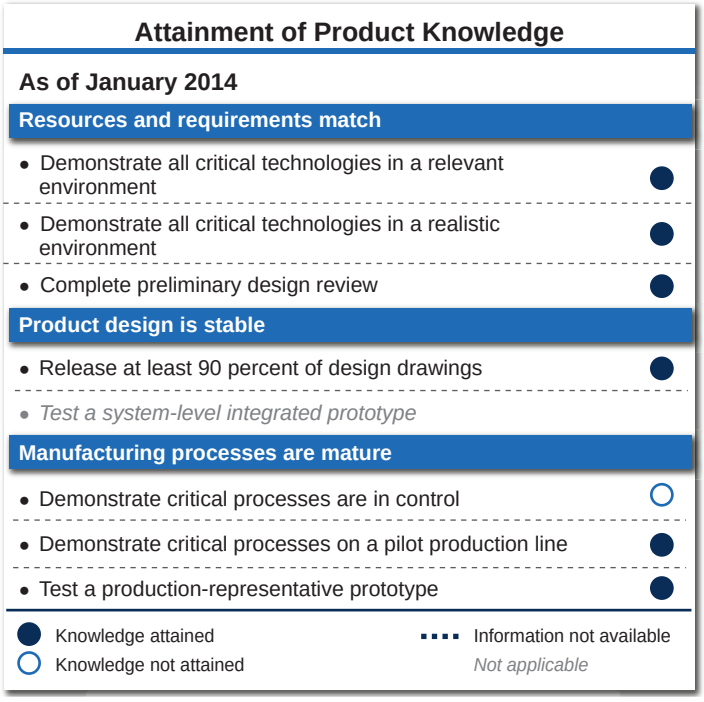
method of monitoring small business participation, as the report includes goals for small business subcontracting. Not all prime contracts for major defense acquisition programs are required to submit individual subcontracting reports. For example, some contractors report small business participation at a corporate level as opposed to a program level and this data is not captured in the individual subcontracting reports. Information gathered for this analysis is presented in appendix VI.

4092 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

AIM-9X Block II Air-to-Air Missile (AIM-9X Block II)

The AIM-9X Block II is a Navy-led program to acquire short-range air-to-air missiles for the F-35, the Navy's F-18, and the Air Force's F-15, F-16, and F-22A fighter aircraft. It is designed to detect, acquire, intercept and destroy a range of airborne threats. Block II includes hardware and software upgrades expected to improve the range from which the AIM-9X can engage targets, target discrimination, and interoperability. It was designated a major defense acquisition program in June 2011.

Source: U.S. Navy.



Program Essentials

Prime contractor: Raytheon Missile Systems
Program office: Patuxent River, MD
Funding needed to complete:
- R&D: $113.2 million
- Procurement: $4,167.0 million
- Total funding: $4,280.2 million
- Procurement quantity: 5,321

Program Performance (fiscal year 2014 dollars in millions)

	As of 12/2011	Latest 09/2013	Percent change
Research and development cost	$178.8	$224.5	25.6
Procurement cost	$4,023.0	$3,568.0	-11.3
Total program cost	$4,201.8	$3,792.5	-9.7%
Program unit cost	$0.700	$0.632	-9.7%
Total quantities	6,000	6,000	0.0
Acquisition cycle time (months)	39	TBD	TBD

The AIM-9X Block II entered production in June 2011 with mature critical technologies, a stable design, and production processes that had been demonstrated on a production line, but were not in control. In July 2013, the Navy suspended operational testing for the AIM-9X Block II due to two issues with missile performance. According to the program office, one issue has been resolved with a software fix. However, the root cause for the second issue, related to probability of kill, a key performance requirement, was still under investigation during our review. The program has stopped accepting missiles until the root cause analysis is complete and the program determines what, if any, fixes to those missiles may be needed. The program also expects to delay the full-rate production decision from April 2014 until the second quarter of fiscal year 2015.

4093 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

AIM-9X Block II Program

Technology and Design Maturity

The AIM-9X Block II entered operational testing with its critical technologies mature and its design stable. The Block II began as a pre-planned product improvement and various component development and integration efforts have been ongoing since 2004. According to the Navy's May 2011 technology readiness assessment, the Block II involves the integration of mature technologies, including a new active optical target detector/datalink, an upgraded electronics unit, and new operational flight software, among others. These hardware and software upgrades are intended to improve the missile's two-way communication capabilities, its tracking and targeting, its range, and its accuracy. The program estimates that 85 percent of Block II components are unchanged from Block I. In July 2013, the Navy suspended operational testing due to missile performance deficiencies. The root causes of the deficiencies are still under investigation.

Production Maturity

The AIM-9X Block II began production in June 2011 with manufacturing processes that had been demonstrated on a pilot production line, but were not in control. Prior to its production decision, the program concluded that its manufacturing readiness was at the level recommended by DOD guidance, but not at a level that indicated that processes were in control. According to the program office, a production readiness review and manufacturing readiness assessment will occur prior to the full-rate production decision, which has been delayed while the program corrects deficiencies discovered in operational testing. Officials expect that the missile's manufacturing processes will be in control prior to the full rate production decision. In the meantime, the AIM-9X prime contractor has met its internal quality goal for defects per unit, another indicator of production maturity, for the last several months of 2013.

Other Program Issues

The Navy suspended operational testing for the AIM-9X Block II in July 2013 after the program discovered multiple deficiencies that negatively affected missile performance. Officials report this will likely delay the full-rate production decision and initial operational capability to 2015. According to program officials, one of the two issues that led to the suspension of testing related to the missile's target acquisition time, has been addressed through a software change. However, the root cause of the second issue related to its probability of kill—a key performance requirement—is still under investigation. Once the root cause is identified, the program will test the corrections in developmental testing before returning to operational testing. According to program officials, they have stopped accepting missiles from the contractor pending the results of the analysis, but production continues. According to program officials, the AIM-9X Block II program removed 14 missiles from its fiscal year 2013 procurement plans as a result of sequestration reductions. The AIM-9X program plans to pursue a material development decision to initiate a Block III acquisition program to further improve missile performance in 2014.

Program Office Comments

According to program officials, the AIM-9X Block II program is exceeding warfighters' expectations in every way, specifically, in the areas of cost, schedule and performance. The AIM-9X Block II program discovered deficiencies during operational testing and has implemented manufacturing and software improvements that meet or exceed requirements. The program remains on schedule to meet initial operational capability threshold and deliver "game changing capability" in the Beyond Visual Range Air-to-Air Missile employment.

Air and Missile Defense Radar (AMDR)

The Navy's Air and Missile Defense Radar (AMDR) will be a next-generation radar system designed to provide ballistic missile defense, air defense, and surface warfare capabilities. AMDR will consist of an S-band radar for ballistic missile defense and air defense, X-band radar for horizon search, and a radar suite controller that controls and integrates the two radars. AMDR will initially support DDG 51 Flight III. The Navy expects AMDR to provide the foundation for a scalable radar architecture that can be used to defeat advanced threats.

Program Essentials

Prime contractor: Raytheon
Program office: Washington, DC
Funding needed to complete:
R&D: $881.1 million
Procurement: $3,919.8 million
Total funding: $4,800.9 million
Procurement quantity: 22

Program Performance (fiscal year 2014 dollars in millions)

	As of	Latest 10/2013	Percent change
Research and development cost	NA	$1,895.3	NA
Procurement cost	NA	$3,919.8	NA
Total program cost	NA	$5,844.4	NA
Program unit cost	NA	$265.655	NA
Total quantities	NA	22	NA
Acquisition cycle time (months)	NA	158	NA

AMDR entered system development in October of 2013 with all four of its critical technologies approaching full maturity. This was 6 months later than planned, leading to a delay in many of the program's future events. These delays might impact the Navy's plan to design the DDG 51 Flight III, intended to carry the radar. The Navy and shipbuilders have determined that a 14-foot active radar is the largest that can be accommodated by the existing DDG 51 though AMDR is also being developed as a scalable design. A new X-Band portion will be developed under a separate program at a later date, with AMDR initially using a SPQ-9B radar in its place.

4095 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

AMDR Program

Technology and Design Maturity

All four of the AMDR's critical technologies are approaching full maturity and were demonstrated using a 1000-element radar array. The array is a smaller version of the planned AMDR arrays. According to the program, two technologies previously identified as the most challenging—digital-beam-forming and transmit-receive modules, have been demonstrated in a relevant environment. Program officials stated digital-beam-forming is necessary for AMDR's simultaneous air and ballistic missile defense mission. The AMDR's transmit-receive modules—the individual radiating elements of the radar—use gallium nitride technology instead of the legacy gallium arsenide technology for potential efficiency gains. The other two critical technologies are related to software and digital receivers and exciters. Officials stated that software development will require a significant effort. A series of software builds are expected to deliver approximately 1 million lines of code and are designed to apply open system approaches to commercial, off-the-shelf hardware. Integrating the X-band radar will require further software development.

According to officials, much of AMDR's hardware has been demonstrated ahead of the preliminary design review, scheduled for June 2014, though the number of design drawings is still pending. The Navy obtained a waiver to hold this review after the start of system development citing cost concerns and a belief that the prototype array satisfactorily demonstrates AMDR's critical technologies.

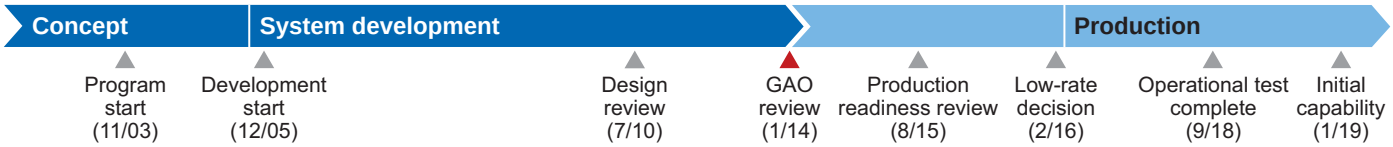
Other Program Issues

AMDR entered system development in October of 2013—6 months later than planned, with corresponding delays to future program milestones. These delays might have an impact on the ability of the AMDR program to maintain its planned schedule for delivery in 2019. Additionally, the delays might also hinder timely delivery of necessary information related to AMDR's parameters, such as power, cooling, and space requirements needed for ongoing and planned design studies related to Flight III development. However, program officials do not anticipate a delay for AMDR's planned 2019 availability for integration into the first planned DDG 51 Flight III. The X-band portion of AMDR will be comprised of an upgraded version of an existing rotating radar (SPQ-9B), instead of the new design initially planned. The new radar will instead be developed as a separate program at a later date and integrated with the thirteenth AMDR unit. According to the Navy, the upgraded SPQ-9B radar fits better within the Flight III's sea frame and expected power and cooling availability. Program officials state that the SPQ-9B radar will have capabilities equal to the new design for current anti-air warfare threats, it will not perform as well against future threats.

The Navy plans to install a 14-foot variant of AMDR on Flight III DDG 51s starting in 2019. According to draft AMDR documents, a 14-foot radar is needed to meet threshold requirements, but an over 20-foot radar is required to fully meet the Navy's desired integrated air and missile defense needs. However, the shipyards and the Navy have determined that a 14-foot active radar is the largest that can be accommodated within the existing DDG 51 deckhouse. Navy officials stated that AMDR is being developed as a scalable design but a new ship would be required to host a larger version of AMDR.

Program Office Comments

The program office concurred with this assessment and provided technical comments which were incorporated where appropriate.



4096 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

CH-53K Heavy Lift Replacement Helicopter (CH-53K)

The Marine Corps' CH-53K heavy-lift helicopter is intended to transport armored vehicles, equipment, and personnel to support operations deep inland from a sea-based center of operations. The CH-53K is expected to replace the legacy CH-53E helicopter and provide increased range and payload, survivability and force protection, reliability and maintainability, and coordination with other assets, while reducing total ownership cost.

Total quantities	156	200	28.2
Acquisition cycle time (months)	119	157	31.9

The CH-53K program continues to move forward toward production, but has not yet fully matured its critical technologies or demonstrated that its design can perform as expected. As a result, the risk of design changes remains. According to program officials, the ground test vehicle has been delivered. However, a number of problems with producibility and qualification of parts have resulted in a delay in production of approximately 6 months and delays to qualification and flight testing.

4097 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

CH-53K Program

Technology Maturity

The CH-53K program began system development in 2005 with immature critical technologies. Nearly 9 years later the program's two critical technologies—the main rotor blade and main gearbox—are approaching maturity. The program expects these technologies to be demonstrated in a realistic environment by its planned February 2016 production decision, a delay in 6 months over last year's schedule. Program officials reported that they conducted a three-blade whirl test that produced results that exceeded required outcomes. Flight testing is expected to begin in late 2014.

Design Maturity

The CH-53K design appears stable, but it has not been demonstrated using a system-level prototype to show that it will perform as expected. The program has reported that they are relying on delivery of test vehicles to demonstrate their design. However, delivery of three of four of those test vehicles is projected to be delayed. Defense Contract Management Agency (DCMA) officials reported that the delays were caused by a number of factors such as late qualification testing, qualification test failures, re-testing, and the qualification of software. The delays have affected aircraft test schedules as well.

Production Maturity

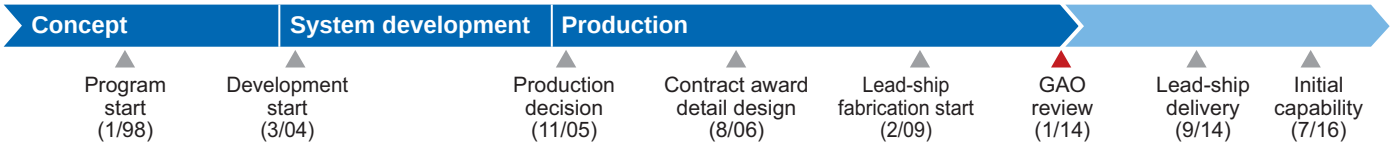
Delivery of the ground test vehicle, which began production in July 2011, took place in October 2012. However, light off of the ground test vehicle—which will include testing of the main gear box and the rotor blades—was delayed until December 2013. Late component deliveries and parts shortages have delayed additional test aircraft deliveries. Test vehicle production is now approximately 10 months behind schedule, which has delayed the program's first test flight by approximately 4 months. These delays also resulted in a 6-month delay for the CH-53K's production decision, which has been moved to February 2016.

Other Program Issues

The CH-53K development contract was modified in April 2013 to reflect a new acquisition program baseline that reflects long standing increases in the program's cost and schedule. The program office reported that part of the increase to the development contract was to include four system demonstration test articles. Program officials reported that in July 2011, the contract's estimated cost increased by $724 million to $3.4 billion. However, recent Defense Contract Management Agency independent cost estimates place the cost closer to $3.7 billion, a total cost increase of approximately $1 billion. The program's schedule contains concurrency between production and testing, which represents risk to the program and may require costly retrofits to aircraft after they have already been produced.

Program Office Comments

In commenting on a draft of this assessment, the program office provided technical comments, which were incorporated as appropriate.



4098 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

DDG 1000 Zumwalt Class Destroyer (DDG 1000)

The Navy's DDG 1000 destroyer is a multimission surface ship designed to provide advanced capability for littoral operations and land-attack in support of forces ashore. The ship will feature a low radar profile and an advanced gun system. The lead ship was launched in October 2013 and the ship (comprised of the hull and mechanical and electrical systems) is currently scheduled for delivery in September 2014, with activation of the mission systems starting in 2015. Fabrication is underway on the remaining two ships in the class.

Program office: Washington, DC
Funding needed to complete:
- R&D: $569.4 million
- Procurement: $768.8 million
- Total funding: $1,338.2 million
- Procurement quantity: 0

Program Performance (fiscal year 2014 dollars in millions)

	As of 1/1998	Latest 08/2013	Percent change
Research and development cost	$2,395.9	$10,593.2	342.2
Procurement cost	$34,205.7	$11,406.4	-66.7
Total program cost	$36,601.6	$21,999.6	-39.9
Program unit cost	$1,143.799	$7,333.213	541.1
Total quantities	32	3	-90.6
Acquisition cycle time (months)	128	222	73.4

The DDG 1000 program has made progress in developing its critical technologies and the ship design is largely mature. While few design changes resulted from lead ship construction, the Navy decided to build the third ship's deckhouse and hangar with steel rather than composite materials due to manufacturing and integration challenges on the first two ships and as a long-term cost saving measure. The program is also incorporating technical configuration changes to maintain capability and minimize cost. Delivery of the lead ship (hull, mechanical and electrical systems) may slip past the currently scheduled date of September 2014 due to difficulties in completing the ship's electrical systems which is impacting test and activation events.

4099 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

DDG 1000 Program

Technology Maturity

The DDG-1000 program has made progress in developing its critical technologies. However, only 3 of 11 are mature and the remaining 8 will not be demonstrated in a realistic environment until after installation on the lead ship. Guided flight tests of the gun system's long-range land-attack projectile were successfully completed in October 2013. After significant cost growth and development challenges, all six software releases for the total ship computing environment have been completed and certified to support lead ship activation and delivery and a software spiral update is under contract timed to support initial operating capability. Following a critical Nunn-McCurdy unit-cost breach in 2010, DOD restructured the program and removed the volume search radar from the ship's design. A modified multifunction radar is expected to begin land based testing in 2014, followed by at-sea testing in 2015.

Design and Production Maturity

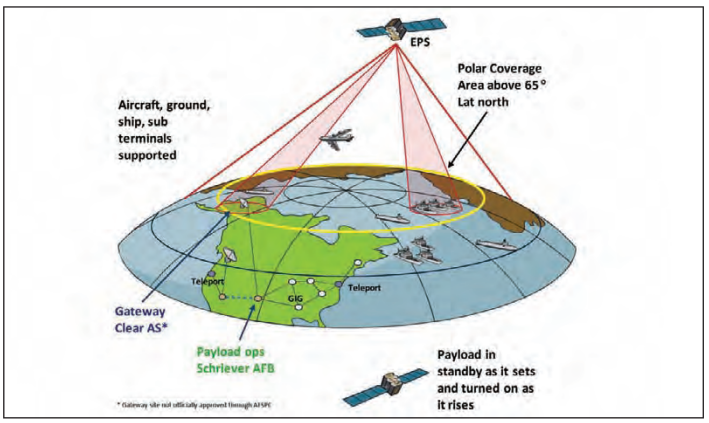
The DDG 1000 design is largely mature. According to the program manager and ship builder, as of October 2013, production and test efforts for the first two ships were 88 and 70 percent complete, respectively. While few design changes have resulted from lead ship construction, shipbuilders have experienced challenges with the manufacture and integration of the composite deckhouse for the first and second ships, resulting in rework and schedule delays particularly on the first ship. The Navy has emphasized a joint inspection process whereby the prime contractors and the Navy validate product quality and completeness prior to integration with the hull. After assessing alternatives and conducting a competition, the Navy decided to build the third ship's deckhouse and hangar with steel as a cost saving measure as the program manager noted that the Navy has better cost insights into the long-term maintenance of steel compared to composite materials.

Other Program Issues

Delivery of the lead ship (hull, mechanical and electrical systems) may slip past the currently scheduled date of September 2014 and the Navy is in the process of assessing the delivery date. If delivery slips past October 2014, the program will breach its acquisition program baseline schedule requirements. According to the Navy, the delay is the result of difficulties in completing the ship's electrical systems, which is impacting test and activation events.

The program has awarded all major contracts for the three ships in the DDG 1000 class among four prime contractors. As the integrator, the Navy is responsible for ensuring on-time delivery of products and bears the costs of schedule delays that affect another contractor. Bath Iron Works is now producing the hull for all three ships. In August 2013, the Navy awarded a fixed price contract to Bath Iron Works for a steel deckhouse, hangar, and aft peripheral vertical launching system for the third ship. According to the program manager, the shipbuilder negotiated a 5- and 10-month delivery delay for the second and third ship, respectively.

Program officials also reported that the program absorbed sequestration reductions of $70 million in fiscal year 2013 by delaying testing and the award of contracts for mission-related equipment. The program is also incorporating technical configuration changes resulting from the configuration steering board and Nunn-McCurdy annual cost review aimed at maintaining capability and minimizing costs. For example, the program manager told us the program assessed alternatives to the close in gun system and chose a legacy system that met requirements with about half the weight and cost.



Program Office Comments

In commenting on a draft of this assessment the Navy noted that the DDG 1000 lead ship was successfully launched in October 2013, a christening is scheduled for April 2014, and activation activities continue. For the second ship, keel laying and hangar erection have occurred, hull integration is underway, and deckhouse delivery is scheduled for spring 2014. The Navy noted that significant integration efforts between four prime contractors continue with a focus on cost reduction and schedule performance. The Navy also provided technical comments, which were incorporated where deemed appropriate.

Enhanced Polar System (EPS)

The Air Force's Enhanced Polar System (EPS) is to provide next-generation protected extremely high frequency (EHF) satellite communications in the polar region. It will replace the current Interim Polar System and serve as a polar adjunct to the Advanced EHF (AEHF) system. EPS is to consist of two EHF payloads hosted on classified satellites, a gateway to connect modified Navy Multiband Terminals to other communication systems, and a control and planning segment (CAPS).

Source: LinQuest Corporation.

Concept | **System development/Production**

Program initiation (12/07)	GAO review (1/14)	Development start (2/14)	Design review (7/14)	Payload-1 on orbit (Q2 FY15)	Payload-2 on orbit (Q2 FY17)	End operational test (2/18)	Operational capability (6/18)

Program Essentials

Prime contractor: Northrop Grumman Information Systems
Program office: Los Angeles AFB, CA
Funding needed to complete:
R&D: $398.1 million
Procurement: $0.0 million
Total funding: $398.1 million
Procurement quantity: 0

Program Performance (fiscal year 2014 dollars in millions)

	As of	Latest 07/2013	Percent change
Research and development cost	NA	$1,505.3	NA
Procurement cost	NA	$0.0	NA
Total program cost	NA	$1,505.3	NA
Program unit cost	NA	$752.625	NA
Total quantities	NA	2	NA
Acquisition cycle time (months)	NA	126	NA

The three segments of the EPS are in various stages of development. Although the EPS program's two payloads are built, funding constraints resulted in reductions to the requirements of the control and planning segment and gateway segment, which delayed initial operational capability by 2 years. However, the reduction of capabilities also reduced the amount of development necessary and allowed for a revised acquisition strategy that, according to the program office, reduced risk and cost.

4101 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

EPS Program

Technology and Design Maturity

EPS was initiated in 2007 to fill a gap identified in the Advanced Polar System study. The Under Secretary of Defense for Acquisition, Technology, and Logistics directed the program to proceed to system development to synchronize the program's payload schedule with the host satellite's production timeline. The host program awarded the payload development contract in July 2008, following an acquisition board equivalent to a system development decision. Payload development proceeded and all six critical technologies are fully mature, according to the program office. Both payloads are built and the first payload is fully integrated into the host satellite, which is currently undergoing system-level testing.

In contrast, the control and planning segment (CAPS) and gateway development was delayed. Because of funding constraints, the program office used a design-to-cost approach to reduce CAPS and gateway development to the minimum capability needed. The revised EPS acquisition strategy incorporating changes to CAPS and gateway development was approved in January 2012. The CAPS design contract was awarded in December 2012, with a planned system development decision in July 2014. The gateway requires integration of existing commercial off-the-shelf and government furnished equipment and is considered low risk by the program office.

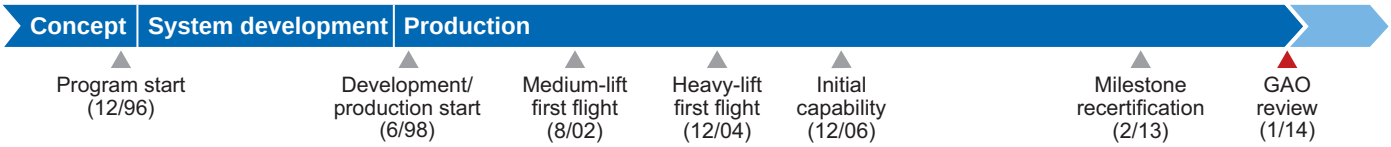
Other Program Issues

The reduction in capabilities for the CAPS and gateway allowed a change in acquisition strategy that reduced cost and risk but also delayed operational capability from fiscal year 2016 to 2018. Under the original acquisition strategy, CAPS was planned as a follow-on increment to the AEHF mission control segment. A sole source award was to be made to AEHF's prime contractor for CAPS, while the gateway was to be competitively awarded. The reduced requirements and revised acquisition strategy allowed for CAPS to be competitively awarded. The reduction of requirements nearly eliminated the development work for the gateway. Consequently, the Navy's Space and Naval Warfare Systems Command (SPAWAR) System Center Pacific will be responsible for integrating, testing, installing, certifying, and sustaining the gateway segment. According to the program office, this approach also reduces cost and schedule as it would take time for a contractor to develop the expertise and test beds that SPAWAR System Center Pacific already has. The reduction in requirements and revised acquisition strategy reduced overall program cost by about $1 billion, according to program officials.

The payloads are expected to be on orbit in fiscal years 2015 and 2017 respectively. By the current schedule, CAPS site installation will occur in late fiscal year 2016. According to the program office, CAPS is not required for payload on-orbit testing, but it is required for inter-segment testing scheduled for the first quarter of fiscal year 2017 and for overall functioning of the EPS system. There is adequate schedule margin according to officials, but any additional delays such as delayed funding or program milestones will result in a further delay in operational capability.

Program Office Comments

In commenting on a draft of this assessment, the program office provided technical comments, which were incorporated where deemed appropriate.



4102 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Evolved Expendable Launch Vehicle (EELV)

The Air Force's EELV program acquires launch services to provide critical space support to DOD, national security, and other government missions. The United Launch Alliance is currently the sole provider of launch vehicles for U.S. military and intelligence satellites. However, the Air Force may certify new launch providers to compete for future launch services. Today, the program consists of two families of launch vehicles, support systems, and launch site operations. We assessed the Atlas V and the Delta IV.

Program Essentials

Prime contractor: United Launch Services, LLC
Program office: El Segundo, CA
Funding needed to complete:
R&D: $81.4 million
Procurement: $42,848.3 million
Total funding: $42,929.7 million
Procurement quantity: 89

Program Performance (fiscal year 2014 dollars in millions)

	As of 10/1998	Latest 08/2013	Percent change
Research and development cost	$1,872.6	$2,460.6	31.4
Procurement cost	$16,403.2	$61,463.2	274.7
Total program cost	$18,275.9	$63,923.7	249.8
Program unit cost	$100.972	$420.551	316.5
Total quantities	181	152	-16.0
Acquisition cycle time (months)	NA	120	NA

We assessed EELV technology as mature with 66 successful launches as of December 2013. We could not assess design or production maturity using our best practices. All of the 14 EELV launch vehicle variants have launched at least once. However, only three variants—the Atlas V 401, the Delta IV Medium, and the Delta IV Heavy—have launched seven times, proving production maturity according to an Aerospace Corporation measure developed for the program. EELV completed recertification after reporting Nunn-McCurdy critical unit cost breaches in the March 2012 Selected Acquisition Report and transitioned back into the production phase in February 2013. The program is estimated to cost over $70 billion through 2030. EELV program officials are currently conducting activities to certify new launch providers and signed a contract modification to procure additional EELV launches.

4103 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

EELV Program

Technology, Design, and Production Maturity

While EELV's technology is mature, we could not assess design and production maturity because the Air Force does not obtain information from the contractor that would facilitate this assessment. According to the Aerospace Corporation's measurement known as the "3/7 reliability rule," once a vehicle variant is launched successfully three times its design can be considered mature. Similarly, if a vehicle is successfully launched seven times, both the design and production process can be considered mature. Based on this rule, few variants have reached maturity for both design and production. Each of the 9 Atlas V variants and the five Delta IV variants has flown at least once, demonstrating the viability of their technologies, and 10 of the Atlas and Delta variants have flown three times, demonstrating design maturity according to Aerospace's rule. However, only 3 of the 14 EELV variants have demonstrated production maturity with seven flights. Until a launch vehicle configuration demonstrates design and production maturity, problems with fleetwide designs or production processes may go undiscovered, which could cause significant cost and schedule risk.

The Air Force is investigating the root cause of an anomaly with the Delta IV upper stage engine which did not perform as expected during a launch in October 2012. According to the EELV program office, the initial phase of the investigation was completed in May 2013 but a root cause determination was not made. While the engine has performed normally on launches in May and August 2013, the Air Force delayed a third launch of the Delta IV scheduled for October 2013, due to new conclusions from the investigation and to fully understand the anomaly and reduce any potential risks.

Other Program Issues

Due to a program restructuring stemming from the Nunn-McCurdy breaches reported in the March 2012 Selected Acquisition Report, the program developed a new acquisition program baseline, which was approved in early 2013. The estimated costs for the program are about $70 billion based on the need for 151 launches through the year 2030. This estimate is around $35.7 billion more than the previous estimate reported in March 2012. The program identified several causes for this cost growth including extension of the program life-cycle from 2020 to 2030, procurement of 60 additional launch vehicles, the inherently unstable nature of the demand for launch services, and industrial base instability.

The Air Force signed a contract modification in December 2013 to procure additional EELV launches and has revised its acquisition strategy to meet some of DOD's EELV-class launch vehicle needs. EELV-class is defined as a vehicle or family of vehicles that can reliably launch a variety of payloads up to 13,500 pounds to geosynchronous earth orbit. The revised strategy outlines how to certify a new provider's launch vehicle based on risk classifications for individual payloads. After a new provider completes its first successful flight, the Air Force will award early integration study contracts for the payloads the vehicle is projected to be capable of launching. In November 2012, the Air Force awarded an EELV-class launch service contract to Space Exploration Technologies (SpaceX), in an effort to support the demonstration of its capabilities as part of the certification process. In September and December 2013, SpaceX launched its first and second vehicles toward certification respectively.

Note: Total quantities include 2,849 increment Ib projectiles.

The Excalibur program has made multiple design changes to address reliability concerns since 2012, including a risk that it may not meet its reliability threshold requirement. The Ib round still does not meet insensitive munitions requirements. According to program officials, however, it does meet military standards and the program has projected test dates to address concerns of the Army Insensitive Munitions Board. The program reduced the number of rounds planned for procurement due to a recommendation in the conference report accompanying the Consolidated and Further Continuing Appropriations Act, 2013 and sequestration but has requested restitution of those funds in fiscal years 2015 and 2016.

4105 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Excalibur Program

Technology and Design Maturity

The Excalibur program's critical technology is fully mature. The program has made multiple incremental design changes intended to increase reliability since the low-rate production decision in 2012. For example, the contractor producing the Global Positioning System (GPS) receiver made hardware and software changes to increase receiver reliability in the gun launch environment. Additionally, the program has made changes to the guidance assembly and the fuze safe and arm device to address failures during Ib round developmental testing. There have been no design changes to the warhead or the operational flight software. The Ib round still does not meet requirements related to insensitive munitions—ensuring that a round will not detonate under any condition other than its intended mission. According to program officials, however, it does meet military standards. The program reports that a follow-up test to meet the Army Insensitive Munitions Board requirements, which was delayed due to sequestration and furloughs during the government shutdown, is projected for early 2014. Ensuring compliance with this requirement could require design changes and the program is uncertain of the total number of drawings that will ultimately be required.

The program reported that it received a funding increase in fiscal year 2014 of $5 million to support the completion of initial operational test and evaluation, which was subsequently reduced due to sequestration for a net increase of $4.3 million. All performance and safety requirements have been met, but reliability testing will not be complete until after production has begun.

Production Maturity

According to program officials, the program is at low risk of not meeting its reliability threshold of 90 percent and at moderate-to-high risk of not meeting its reliability objective. However, given test results since the low-rate decision, the program expects to meet the threshold reliability requirement. The program has been authorized to procure 1800 rounds in low-rate production and will seek authorization to procure the remaining rounds at the full-rate production decision, tentatively scheduled for mid-2014.

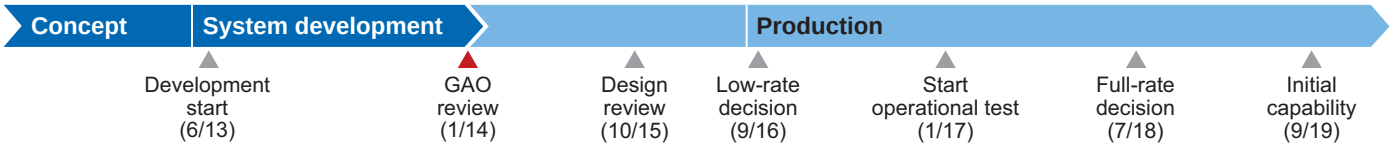
Other Program Issues

The program is still projecting to produce 3,455 Ib rounds, but its fiscal year 2013 procurement funding was cut by $47.5 million due to a recommendation in the conference report accompanying the Consolidated and Further Continuing Appropriations Act, 2013 and sequestration. As a result the program is reporting a 17 percent reduction of rounds for procurement. The program, however, has requested restoration of funding for those rounds in fiscal years 2015 and 2016. The project originally planned for funding to end in fiscal year 2014; spreading funding into future years will increase the life of the program and may have additional costs.

Program Office Comments

In commenting on a draft of this assessment, program officials stated that Excalibur continues to provide commanders with an organic precision targeting capability resulting in over 700 rounds being fired in combat to date. They also stated that the program continues to execute within all acquisition program baseline parameters and is meeting or exceeding all five of its key performance parameters. Excalibur Increment Ib has shown performance improvements and continues to execute to the plan approved by both the Army and joint insensitive munitions board and has seen improvements in the area of less sensitive reactions.

Program officials stated that the final Excalibur increment began low-rate initial production in first quarter fiscal year 2014 and successfully completed first article testing in December 2013. The current Excalibur production contract contains fixed price procurement options to ensure consistent procurement costs through fiscal year 2016. The program also provided technical comments, which were incorporated as appropriate.



4106 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

F-22 Increment 3.2B

The Air Force's F-22 Raptor is a stealthy air-to-air and air-to-ground fighter/attack aircraft. The Air Force established an F-22 modernization and improvement program in 2003 to add enhanced air-to-ground, information warfare, reconnaissance, and other capabilities and to improve the reliability and maintainability of the aircraft. Increment 3.2B, the fourth increment of the modernization program, was initially managed as part of the F-22 baseline program, but is now being managed as a separate major defense acquisition program.

Program Essentials

Prime contractor: Lockheed Martin
Program office: Wright-Patterson AFB, OH
Funding needed to complete:
R&D: $543.1 million
Procurement: $339.1 million
Total funding: $882.2 million
Procurement quantity: 143

Program Performance (fiscal year 2014 dollars in millions)

	As of 06/2013	Latest 09/2013	Percent change
Research and development cost	$1,222.1	$1,218.8	-0.3
Procurement cost	$344.6	$339.1	-1.6
Total program cost	$1,566.7	$1,557.9	-0.6
Program unit cost	$10.308	$10.249	-0.6
Total quantities	152	152	0.0
Acquisition cycle time (months)	72	75	4.2

Increment 3.2B is an enhancement to the F-22, bringing upgraded electronic protection, geolocation, and intra-flight data link capabilities, and integrating AIM-9X and AIM-120D missiles. The Air Force received approval to begin system development of Increment 3.2B as a separate major defense acquisition program in June 2013. The one reported critical technology has been demonstrated in a relevant, but not a realistic, environment. Full maturity is expected by the critical design review in October 2015, by which point the Air Force also anticipates achieving full design stability. There may be a production gap of two to four years between qualification of hardware for the program and the beginning of low-rate initial production. The program office stated that it has mitigated risk related to AIM-9X software development.

4107 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

F-22 Inc 3.2B Program

Technology and Design Maturity

Increment 3.2B's sole, identified critical technology, a geolocation algorithm, is not yet fully mature having been demonstrated only in a relevant environment. The program office expects the technology to reach full maturity by October 2015. The Air Force also anticipates achieving full design stability by the October 2015 critical design review as 92 percent of system level drawings are currently releasable. A knowledge-based acquisition approach is a cumulative process, and mature technology is a prerequisite for moving into system development. The program intends to demonstrate that the design can perform as expected by integrating and testing all key subsystems and components prior to the critical design review.

Production Maturity

Prior to system development, DOD systems engineering personnel identified a production gap of two to four years between qualification of hardware for Increment 3.2B and the beginning of low-rate initial production as a risk as some of the electronic components used may no longer be available when production begins. The program office stated that it is working closely with suppliers to mitigate identified risks through an advance procurement contract. Program officials partly attributed the gap to an early start made on hardware development given initial assumptions about the amount of development involved. Additionally, the Defense Contract Management Agency has noted supplier developmental issues with displays and processing modules which support Increment 3.2B.

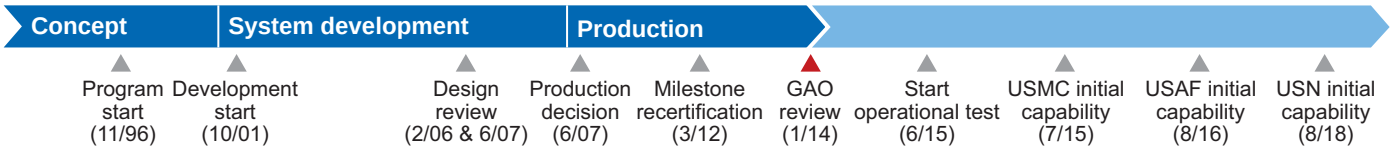
Other Program Issues

Consistent with direction from Congress and the Office of the Secretary of Defense, the Air Force designated F-22 Increment 3.2B as a distinct major defense acquisition program rather than managing it as part of the F-22 baseline program. About half of the program's $1.2 billion estimated development cost was spent under the F-22 baseline program. Originally scheduled for December 2012, the approval to formally initiate the Increment 3.2B acquisition program and begin system development was delayed until June 2013 as it took longer than expected to prepare Air Force and independent cost estimates. According to cost estimators, the delay is attributable to their having to reconstruct missing cost information from prior modernization increments in order to estimate costs for Increment 3.2B.

An initial risk assessment noted that if the Increment 3.2B program did not receive the customized software that allows the F-22 to use the AIM-9X air-to-air missile in time for operational testing, it might face a delay in its overall fielding schedule. The F-22 program office stated that it has mitigated risk related to missile software development, and has signed an agreement with the AIM-9X program office on technical and schedule requirements for integrating the missile. The F-22 program office plans to field limited AIM-9X capabilities prior to the completion of Increment 3.2B by including them as part of an earlier software update.

Program Office Comments

The Air Force provided technical comments, which were incorporated as appropriate.



4108 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

F-35 Lightning II Program (F-35)

DOD's F-35 program is developing a family of stealthy, strike fighter aircraft for the Navy, Air Force, Marine Corps, and U.S. allies, with the goal of maximizing commonality to minimize life-cycle costs. The carrier-suitable variant will complement the Navy F/A-18E/F. The Air Force variant is expected to replace the air-to-ground attack capabilities of the F-16 and A-10, and complement the F-22A. The short take-off and vertical landing (STOVL) variant is expected to replace the Marine Corps F/A-18 and AV-8B aircraft.

Program Essentials

Prime contractor: Lockheed Martin, Pratt and Whitney
Program office: Arlington, VA
Funding needed to complete:
R&D: $5,516.9 million
Procurement: $231,243.5 million
Total funding: $239,559.1 million
Procurement quantity: 2,293

Program Performance (fiscal year 2014 dollars in millions)

	As of 10/2001	Latest 08/2013	Percent change
Research and development cost	$40,995.1	$61,795.8	50.7
Procurement cost	$181,875.9	$266,469.1	46.5
Total program cost	$224,774.7	$332,320.0	47.8
Program unit cost	$78.428	$135.254	72.5
Total quantities	2,866	2,457	-14.3
Acquisition cycle time (months)	116	237	104.3

Although the F-35 program has invested billions of dollars and ordered 150 production aircraft, gaps in product knowledge persist. Four critical technologies are not mature and the program continues to experience design changes. Development testing is progressing but is far from complete and will likely drive more changes in design and manufacturing processes. While manufacturing efforts are improving, only twenty-five percent of the program's critical manufacturing processes are mature and capable of consistently producing quality parts, and fewer planes were produced in 2013 than initially planned. Software development has progressed; but if additional delays are encountered initial operating capability dates could be at risk. Long-term affordability and sustainment costs remain challenging.

4109 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

F-35 Program

Technology Maturity

Three of the program's critical technologies are nearing maturity while one is immature. The program has made progress addressing technical risks including the helmet mounted display, which is needed for the aircraft to fully perform its missions, and the Autonomic Logistics Information System (ALIS), which is critical to the operations and sustainment of the fleet. The program recently chose to end development of an alternate helmet due to progress made on the original helmet design and work on development of a newer generation helmet. ALIS integration and testing continues with the next, more capable version expected to be delivered in 2014.

Design Maturity

Although the three aircraft designs were not stable at critical design reviews in 2006 and 2007, all expected engineering drawings have since been released. However, issues discovered in testing continue to drive design changes. In 2013, bulkhead and rib cracks were discovered in the STOVL variant that may require the program to make changes to production and retrofit aircraft. The carrier variant's new arresting hook system successfully completed a critical design review and is expected to be ready for carrier use by October 2014. With significant testing remaining, additional design changes are likely.

Production Maturity

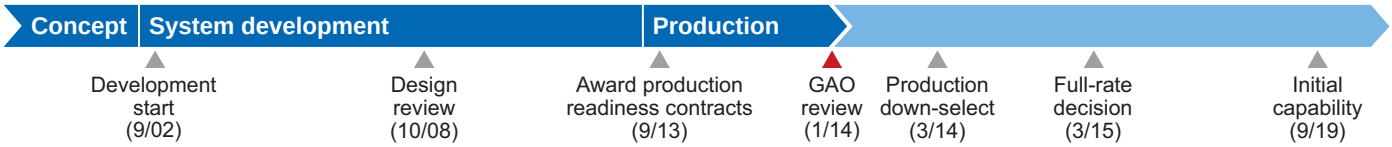
DOD has invested about $35 billion in procuring 150 aircraft through 2013. The contractor uses statistical process controls as one means to assess critical manufacturing processes. Twenty five percent of those processes are currently judged capable of consistently producing quality parts at the best practice standards. Production efforts have improved as the production line continues to show efficiencies and quality metrics show positive trends. However, in 2013, problems with engine hoses, engine turbines, and specialty metals halted production deliveries for three months. In 2013, 35 planes were delivered to the government—eight less than originally planned. Aircraft deliveries were postponed for one month while the runway at the final assembly facility was resurfaced.

Other Program Issues

In 2013, the military services re-established initial operating capability dates for their respective F-35 variants. To achieve those dates, the Marine Corps and Air Force will accept basic warfighting capabilities provided by software Blocks 2B and 3I respectively, while the Navy intends to wait for the full suite of capabilities provided by software Block 3F. Block 2B development is currently behind schedule, which could impact the development of Block 3I, and subsequently 3F. Any additional software delays could put initial operating capability dates at risk as software is essential to achieve aircraft capabilities such as sensor fusion, weapons and fire control, maintenance diagnostics, and propulsion. In addition, the program's long-term affordability remains a challenge. The amount of annual funding required to complete development and procurement of the F-35 is more than $12 billion on average, while the cost to operate and support the aircraft is estimated at more than $1 trillion over its life-cycle. These estimates may change over time as testing progresses and more concrete information becomes available.

Program Office Comments

In addition to providing technical comments, the program noted that it appreciates GAO's reviews in assisting the program by identifying areas for improvement. The program has made great strides in the past year to further stabilize technology, design, and production maturity, and work continues on identified areas to improve program performance. The program ended development of the alternate F-35 helmet as further testing indicated it is acceptable for USMC initial operating capability. Continued improvements will be made in the Gen III helmet. This decision includes a guarantee from industry to reduce the unit cost by 12 percent from previous estimates. Aircraft and engine quality continues to improve as manufacturing processes mature, and unit costs continue to come down lot over lot. The program has taken steps to improve management of concurrency risk and minimize costs to the services by reducing the time required to implement changes into the production line so that fewer aircraft need post-production retrofits.



4110 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Family of Beyond Line-of-Sight - Terminals (FAB-T)

The Air Force's FAB-T program plans to provide a family of satellite communications terminals for airborne and ground-based users to replace many program-unique terminals. It is being designed to work with current and future communications capabilities and technologies. FAB-T is expected to provide voice and data over military satellite communications for nuclear and conventional forces through ground command posts and E-6 and E-4 aircraft, and was originally planned to provide force element capabilities on B-2, B-52, and RC-135 aircraft.

Program Essentials

Prime contractor: Boeing, Raytheon
Program office: Bedford, MA
Funding needed to complete:
R&D: $196.0 million
Procurement: $2,190.6 million
Total funding: $2,386.6 million
Procurement quantity: 216

Program Performance (fiscal year 2014 dollars in millions)

	As of 12/2006	Latest 10/2013	Percent change
Research and development cost	$1,616.7	$2,406.0	48.8
Procurement cost	$1,736.9	$2,212.0	27.4
Total program cost	$3,353.6	$4,618.0	37.7
Program unit cost	$15.526	$18.772	20.9
Total quantities	216	246	13.9
Acquisition cycle time (months)	129	204	58.1

The latest cost data do not reflect the current cost of the program and the latest quantities do not reflect recent program decisions. A new acquisition program baseline has not yet been approved.

The program is approaching a production decision with a stable, demonstrated design but without having conducted key assessments. Due to continued cost and schedule growth in developing this design, the Air Force signed a development contract with an additional vendor in September 2012 to establish an alternate source for a system with capabilities similar to the original vendor's FAB-T effort. An acquisition baseline updated to reflect the award to a second vendor, and other changes to the program strategy since 2010, has been delayed and will not be approved until after the Air Force determines which vendor will move forward into production. Despite numerous changes to the program, an independent cost estimate has not been conducted since 2009, but is expected in early 2014.

4111 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

FAB-T Program

Technology Maturity

According to the program office, all of the critical technologies for both vendors are fully mature based on the vendors' self-assessments. The program does not currently plan to conduct an independent technology readiness assessment for the alternate vendor. The program office also stated that both vendors have functional prototypes being utilized for testing.

Design Maturity

According to the program office, FAB-T's design is stable for both the original and alternate vendor development programs. The original vendor completed functional qualification testing in August 2013. The alternate vendor completed a system-level design review in June 2013 and demonstrated a system-level integrated prototype in October 2013.

Production Maturity

In 2012, FAB-T's acquisition strategy was changed to initiate two possible production paths: one providing both command and force element terminals, and the other only command terminals. Both vendors submitted proposals to compete for both approaches. In December 2013, the Air Force chose to pursue the command terminal only approach and the program plans to make a down-select decision to one vendor in the second quarter of fiscal year 2014. Depending on which vendor is chosen, the low-rate production decision is planned for either March 2014 or September 2014.

A 2012 acquisition decision memorandum called for several steps before the award of FAB-T's production contracts, including: an independent cost estimate; a revised acquisition program baseline; and a defense acquisition board review. Program officials stated that neither the cost estimate nor the revised baseline will be completed prior to the down-select decision. Department officials stated that the review has been delayed and not yet rescheduled. Also, FAB-T does not plan to independently assess manufacturing readiness levels prior to the down-select decision. Air Force decisions to commit to a production contractor before the program is fully assessed introduce additional acquisition risk.

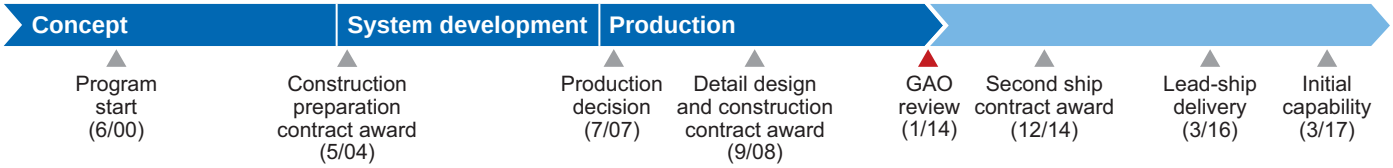
Other Program Issues

In October 2010, an independent review team noted that the program was likely in breach of critical Nunn-McCurdy unit cost thresholds but a breach has not yet been reported by the program. In 2012, the FAB-T program made several revisions to its acquisition strategy—including modification of the original development contract from cost plus award fee to firm fixed-price and the addition of competition by awarding the alternate vendor contract in response to these concerns about cost growth. However, a new acquisition program baseline and independent cost estimate that reflect these changes and their projected costs will not be completed until 2014.

According to Department officials, the requirement for the force element terminals remains in the program but is not currently funded. If not integrated with the B-2 and B-52 bomber platforms, FAB-T may not meet its full range of planned communications capabilities as some are based on the interaction of bomber aircraft with intelligence, surveillance, and reconnaissance aircraft and command terminals.

Program Office Comments

According to program officials, the FAB-T program office continued to execute the revised acquisition strategy in 2013. Significant progress was made by both contractors on their respective development contracts. With respect to production efforts, production planning contracts were awarded to lock down prices. In addition, the competition for command terminals is on-going, and the Air Force has scheduled a down select decision in the second quarter of fiscal year 2014. The independent cost estimate and acquisition program baseline will then be updated to re-baseline the program. To address the cost thresholds and breach concerns, program officials said they are confident that adequate technology and manufacturing assessments, along with the revised cost and schedule evaluation, will be conducted prior to the decision to exercise the first production option. The program office's assessment is that there will be a stable and mature design, with a reliable manufacturing process, to proceed into operational unit production for this critical operational capability.



4112 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Gerald R. Ford Class Nuclear Aircraft Carrier (CVN 78)

The Navy's CVN 78 class of nuclear-powered aircraft carriers is designed to improve operational efficiency, enable higher sortie rates, and reduce manpower through the use of advanced propulsion, aircraft launch and recovery, and survivability technologies. The lead ship, CVN 78, was 70 percent complete at launch; however, its delivery is delayed until March 2016. Also, contract negotiations prompted the Navy to defer the construction contract for CVN 79 until early fiscal year 2015.

R&D: $533.6 million
Procurement: $16,971.8 million
Total funding: $17,508.7 million
Procurement quantity: 1

Program Performance (fiscal year 2014 dollars in millions)

	As of 04/2004	Latest 08/2013	Percent change
Research and development cost	$5,051.9	$4,867.4	-3.7
Procurement cost	$32,363.3	$31,081.1	-4.0
Total program cost	$37,415.2	$36,008.1	-3.8
Program unit cost	$12,471.733	$12,002.694	-3.8
Total quantities	3	3	0.0
Acquisition cycle time (months)	137	155	13.1

The Navy awarded a construction contract for CVN 78 in September 2008 when only 5 of the ship's 13 current critical technologies were mature and the ship's three-dimensional (3D) product model was incomplete. Since then, the lead ship's procurement costs have grown by over 22 percent, from $10.5 billion to $12.8 billion. At present, 7 of the currently planned technologies are mature, with the rest approaching maturity, and the ship's 3D product model is complete. However, maintaining design stability depends on currently immature technologies fitting within the space, weight, cooling, and power reservations allotted them within the ship. Construction to date has been impeded by critical technology system delays, material shortages, and engineering challenges.

4113 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

CVN 78 Program

Technology Maturity

According to the Navy, 7 of the 13 critical technologies for CVN 78 are mature, and the remaining 6 are approaching maturity. To meet required installation dates aboard CVN 78, the Navy produced several of these technologies, such as the volume search radar (VSR), prior to demonstrating their maturity—a strategy GAO's prior work has shown introduces risk of late and costly design changes and rework. The VSR is a component of the dual band radar (DBR), which has been delivered to CVN 78, and is undergoing design modifications needed to complete shipboard integration. According to the Navy, testing in the spring of 2015 will show whether these modifications were successful or a more extensive redesign of the system is required, which could delay DBR deliveries by up to 4 years. Deficiencies affecting water twister components—used to absorb energy when arresting aircraft—of the advanced arresting gear (AAG) technology continue to disrupt the system's development. Recent water twister redesign proved unsuccessful in testing last year. The Navy resolved problems with the redesign and is planning for concurrent testing. Despite these steps, the Navy forecasts AAG land-based testing to be complete in August 2016—a new delay of nearly two years—and after the Navy has accepted CVN 78 delivery. The electromagnetic aircraft launch system (EMALS) has successfully launched aircraft during land-based testing using a single launcher and four motor generators. The shipboard system will employ a more complex configuration with more launchers and generators sharing a power interface.

Design Maturity

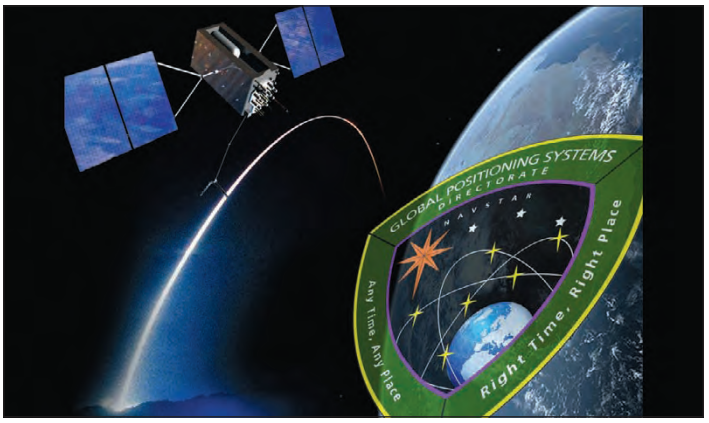
CVN 78 completed its 3D product model in November 2009—over a year after the construction contract award. While the model is now considered functionally complete, maintaining design stability depends on technologies fitting within the space, weight, cooling, and power reservations allotted them. Shipboard testing may reveal a need for design changes. Also, as construction progresses, the shipbuilder is discovering "first-of-class" type design changes, which it is using to update the model prior to CVN 79 construction.

Production Maturity

According to program officials, CVN 78 is approximately 70 percent complete. Lead ship procurement costs for the lead ship have grown by over 22 percent since construction authorization in fiscal year 2008 due in part to problems encountered in construction. Out-of-sequence work driven largely by material shortfalls, engineering challenges, and delays developing and installing certain critical technologies the Navy provides to the shipbuilder for installation has affected construction progress.

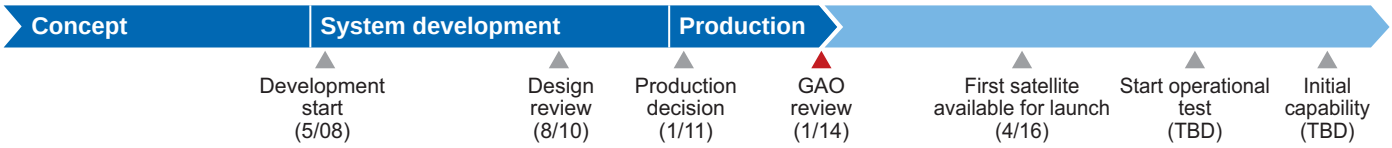
Other Program Issues

The Navy deferred award of the CVN 79 detail design and construction contract from late fiscal year 2013 to the first quarter of fiscal year 2015. According to the Navy, continuing contract negotiations provide an opportunity to incorporate process improvements into construction plans. The Navy has undertaken an in-depth review of CVN 79 requirements and capabilities to identify cost trades, which it hopes can facilitate an agreement on contract terms. These actions are consistent with recommendations we made in September 2013 to defer the CVN 79 construction contract and to conduct a cost-benefit analysis on Ford-class capability requirements and the time and money needed to field systems to provide these capabilities.



Program Office Comments

According to the program office, CVN 78 displaced 77,000 tons and was 70 percent complete at launch—the highest levels achieved in aircraft carrier new construction. The program office also reported that labor inefficiencies during ship erection are past and the principal risk remaining is in shipboard testing. Concerns over system integration within platform space, weight, and power reservations have been resolved. Land based testing for EMALS and DBR has progressed enough that program officials do not anticipate significant redesign. Further, the AAG test schedule remains on track to support ship delivery and sea trials. Lastly, the Navy plans to modify the CVN 79 construction preparation contract to extend the terms of the contract and avoid a production break during negotiations on the detail design and construction contract without delaying ship delivery. Program officials also provided technical comments that were incorporated where deemed appropriate.



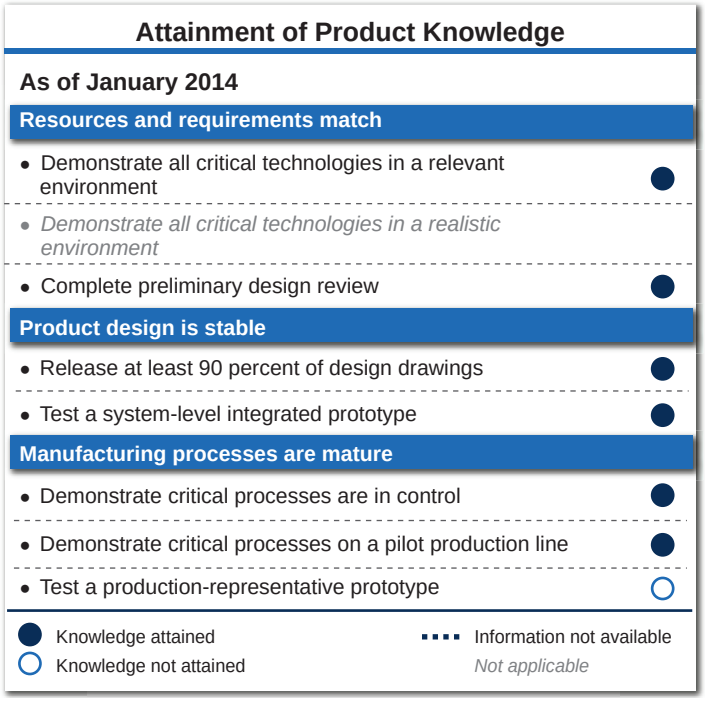
4114 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Global Positioning System III (GPS III)

The Air Force's Global Positioning System III (GPS III) program plans to develop and field a new generation of satellites to supplement and eventually replace GPS satellites currently in use. Other programs are developing the ground system and user equipment. GPS III is to be developed incrementally. We assessed the first increment, which intends to provide capabilities such as a stronger military navigation signal to improve jamming resistance and a new civilian signal that will be interoperable with foreign satellite navigation systems.

Source: U.S. Air Force.

Program Essentials



Prime contractor: Lockheed Martin
Program office: El Segundo, CA
Funding needed to complete:
R&D: $261.2 million
Procurement: $495.4 million
Total funding: $756.6 million
Procurement quantity: 2

Program Performance (fiscal year 2014 dollars in millions)

	As of 05/2008	Latest 11/2013	Percent change
Research and development cost	$2,654.8	$2,795.0	5.3
Procurement cost	$1,490.5	$1,581.5	6.1
Total program cost	$4,145.4	$4,376.5	5.6
Program unit cost	$518.169	$547.059	5.6
Total quantities	8	8	0.0
Acquisition cycle time (months)	NA	NA	NA

We could not calculate acquisition cycle times for the first increment of the GPS III program because initial operational capability will not occur until satellites from a future increment are fielded.

The GPS III program's eight critical technologies have been assessed as mature, but three have yet to complete qualification testing. The program reported that its design and production processes are currently mature and a prototype was constructed to reduce risk. However, design changes have been required due to issues identified in testing. Late hardware delivery resulted in delayed testing of the prototype. The GPS III program delayed the first space vehicle's availability for launch from April 2014 to April 2016—a 24 month delay—due to late hardware deliveries and technical problems identified in testing.

4115 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

GPS III Program

Technology and Design Maturity

The program office reports that all eight of its critical technologies are mature and that its design is stable. Three of the GPS III critical technologies, including the timekeeping system and the key GPS signal generator, have not yet completed qualification testing, which is behind schedule. Based on the number of design drawings released to manufacturing, the design has been mature since the program's 2010 design review. However, design changes have been required due to problems identified in testing of key components. The program office reported that it has demonstrated that the design can meet requirements by testing a system-level integrated prototype that includes all key subsystems and components just with less redundancy in the GPS III satellites.

Production Maturity

At the time of GPS III's production decision, the program office reported a level of manufacturing process maturity that indicated its processes were in control and production could begin. However, a complete GPS III satellite was not tested prior to the production decision nor has one been tested to date. To mitigate risk, the program developed a prototype to prove out production processes prior to integrating and testing the first space vehicle. Delivery of the prototype's navigation payload was delayed by a year, which the program office acknowledged resulted in some concurrency in developing and integrating the prototype and the first space vehicle. Program officials stated that the prototype helped the program identify problems and reduce assembly time required for the first space vehicle.

Other Program Issues

The program office recently moved its estimate for the first space vehicle's available for launch date from April 2014 to April 2016—a 24 month delay. This delay was in part driven by late hardware deliveries and multiple technical problems identified in testing, which have also negatively affected costs. The program office stated that the navigation payload for the first GPS satellite was delivered over a year late. The program is still working to address technical problems associated with the mission data unit, the brain of the GPS III navigation mission. Testing revealed radio frequency isolation issues, which can result in signal degradation.

This delay more closely aligns the space vehicle's delivery with the availability of GPS III's ground system, GPS Operational Control Segment (OCX). The synchronization of GPS III's and OCX's schedules continues to be a risk. GPS III satellites cannot be integrated into the constellation or be considered operational until OCX Block 1 is delivered, which is planned for October 2016.

The program is considering dual launching GPS III satellites, potentially beginning as early as the fifth GPS III space vehicle. Our prior work has shown that design changes during production can have significant cost and schedule consequences, including expensive retrofitting and production delays.

Program Office Comments

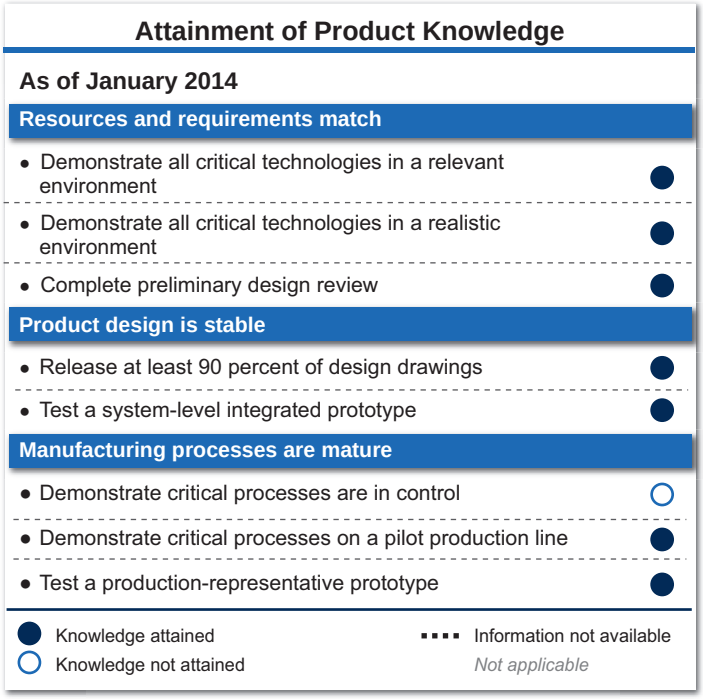
The Air Force also provided technical comments, which were incorporated where deemed appropriate.

4116 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Ground/Air Task Oriented Radar (G/ATOR)

The Marine Corps' Ground/Air Task Oriented Radar (G/ATOR) is an active electronic scanned array three-dimensional short/medium range multi-role radar designed to detect cruise missiles, air breathing targets, rockets, mortars, and artillery. It replaces five different legacy radars. G/ATOR is a block acquisition; later blocks are mostly software upgrades. According to the program office, developmental testing concluded in August 2013, and a low-rate production decision took place in January 2014, followed by a March 2014 contract award.

Source: U.S. Marine Corps.



Program Essentials

Prime contractor: Northrop Grumman
Program office: Quantico, VA
Funding needed to complete:
- R&D: $285.9 million
- Procurement: $2,089.4 million
- Total funding: $2,381.5 million
- Procurement quantity: 55

Program Performance (fiscal year 2014 dollars in millions)

	As of 08/2005	Latest 09/2013	Percent change
Research and development cost	$372.4	$981.1	163.5
Procurement cost	$1,169.3	$1,668.7	42.7
Total program cost	$1,541.7	$2,656.1	72.3
Program unit cost	$24.089	$46.597	93.4
Total quantities	64	57	-10.9
Acquisition cycle time (months)	66	133	101.5

The G/ATOR technologies are mature and its design is stable and demonstrated but its production processes are not yet mature. In addition, the program's reliability is beneath the value needed to meet requirements due to software issues. To address this shortfall, the program plans to develop and incorporate software fixes into low-rate initial production. There may be insufficient time to test all fixes prior to the start of production. Production processes were demonstrated on a pilot production line, but they did not demonstrate stable, adequate control. The program office intends to award a contract for four low-rate production systems in March 2014. According to the program office, these systems are needed to conduct operational and environmental testing in order to meet the initial operational capability.

4117 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

G/ATOR Program

Technology Maturity

All six G/ATOR critical technologies are fully mature. However, according to the program office, testing revealed issues with the radar's software causing it to require a reboot more frequently than anticipated. The problems are driven by a number of lower-level software issues with system startup, random crashes, operator control console freezes, and an unstable command and control interface. The G/ATOR program office has put together a plan to incorporate software fixes to correct system start up and prevent crashes. Some hardware alterations may be required. The program office plans to increase and improve system performance by upgrading the software integration lab to support accelerated testing and conducting field testing with users every six months to demonstrate reliability growth and operational relevance. In addition, the gallium nitride technology, which will be used to upgrade the radar's transmit and receiving modules, is maturing on schedule. This new semi-conductor technology is expected to achieve better performance at a lower cost and will be installed on the last low-rate production lot.

Design Maturity

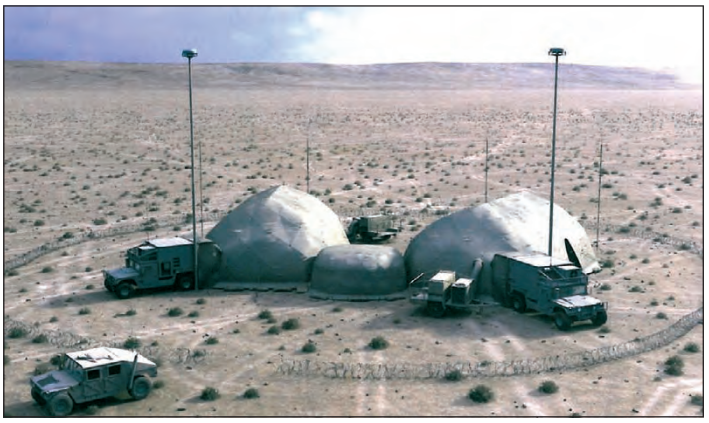
According to the program office, the G/ATOR design is mature, with 100 percent of design drawings released and testing of system-level prototypes completed in August 2013, well after the critical design review but before the program enters production. Risk of additional design changes exists, due to modifications planned for the production units. If these modifications are not incorporated into the design and tested before beginning production, there may be schedule delays if the program chooses to continue production and retrofit systems at a later date.

Production Maturity

According to the program office, the G/ATOR production readiness review was completed in September 2013 and the program demonstrated that its manufacturing processes meet DOD's requirement for the start of low-rate production. However, the manufacturing readiness level does not indicate that its production processes are stable and in control as preferred by commercial best practices. The program plans to begin low-rate production with four systems in March 2014. According to program officials, these systems are needed to conduct developmental, operational, and environmental qualification testing in order to meet the scheduled Block I initial operational capability.

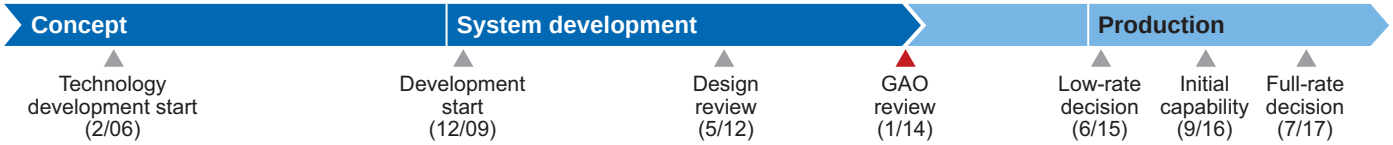
Other Program Issues

The program is authorized to procure 57 G/ATOR systems; however, only 45 were funded in the fiscal year 2014 President's budget. According to the program office, the 12 unfunded G/ATOR systems will require funding by fiscal year 2016 in order to meet initial operational capability. In addition, the concurrent development and production of G/ATOR may be adversely affected by personnel shortages caused, in part, by the impending retirement of highly experienced acquisition workforce staff.



Program Office Comments

In commenting on a draft of this assesment, the program office noted that in October 2011, G/ATOR's performance requirements were revised, which resulted in a re-designation of the program to a major defense acquisition program. At that time, cost estimates were rebaselined; since then G/ATOR has remained on schedule and its total estimated cost decreased. This reduction is due, in part, from implementing better buying power and should cost initiatives. Technical comments were provided by the program office, which were incoporated where deemed approrpiate.

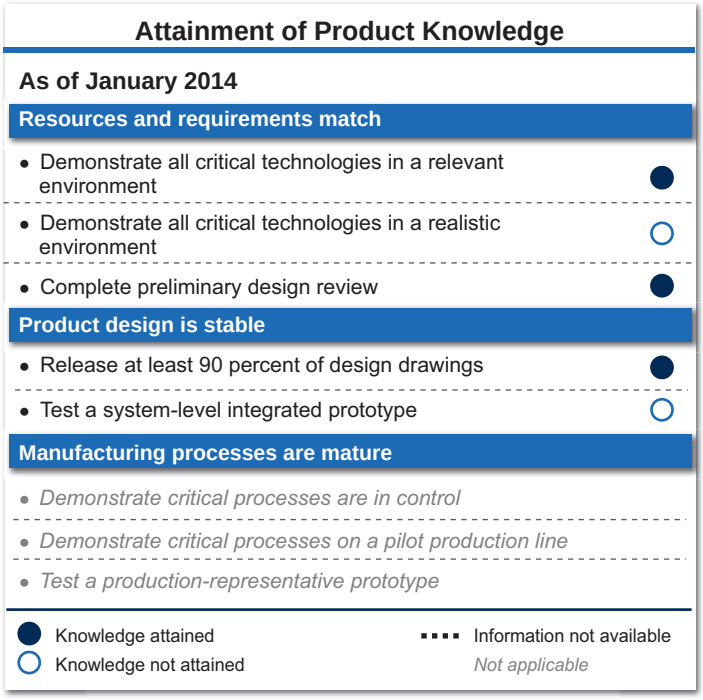


4118 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Integrated Air and Missile Defense (IAMD)

The Army's Integrated Air and Missile Defense (IAMD) program is being developed to network sensors, weapons, and a common battle command system across an integrated fire control network to support the engagement of air and missile threats. The IAMD Battle Command System (IBCS) will provide a capability to control and manage IAMD sensors and weapons, such as the Sentinel radar and Patriot launcher and radar, through an interface module that supplies battle management data and enables networked operations.

Source: Northrop Grumman.



Program Essentials

Prime contractor: Northrop Grumman Space & Mission Systems Corp, Raytheon Integrated Defense Systems
Program office: Huntsville, AL
Funding needed to complete:
R&D: $1,188.0 million
Procurement: $3,399.0 million
Total funding: $4,587.0 million
Procurement quantity: 431

Program Performance (fiscal year 2014 dollars in millions)

	As of 12/2009	Latest 12/2012	Percent change
Research and development cost	$1,677.7	$2,405.0	43.4
Procurement cost	$3,611.0	$3,399.0	-5.9
Total program cost	$5,288.7	$5,804.0	9.7
Program unit cost	$17.867	$12.984	-27.3
Total quantities	296	447	51.0
Acquisition cycle time (months)	80	81	1.2

IAMD completed its critical design review in May 2012 with a stable design and technologies nearing full maturity, but does not plan to demonstrate the design can perform as expected until February 2014. IAMD's mission has not changed, but changes to its plans for integrating with other systems has significantly increased the size of its software effort, delayed its subsystem design reviews and increased development costs by over $717 million. These changes include adding Patriot launcher and radar functionality directly onto the integrated fire control network and increasing the number of units by 146 to 431 total units. WIN-T integration is also a significant risk.

4119 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

IAMD Program

Technology Maturity

Program officials estimate that IAMD technologies will not be fully mature until its planned production decision in 2015. The IAMD program entered system development in December 2009 with its four critical technologies—integrated battle command, integrated defense design, integrated fire control network, and distributed track management—nearing maturity, according to an Army technology readiness assessment based on a notional design. The Army updated the technology readiness assessment in March 2011 based on the winning contractor's design and reached the same conclusion about the technologies' maturity. The Office of the Assistant Secretary of Defense for Research and Engineering concurred with the assessment, but noted that integration with the Warfighter Information Network-Tactical (WIN-T) is a significant risk. It also noted that the assessment was based on modeling and simulations of WIN-T and assumptions about performance. As a result, it recommended realistic, full-scale testing with WIN-T prior to a production decision.

Design Maturity

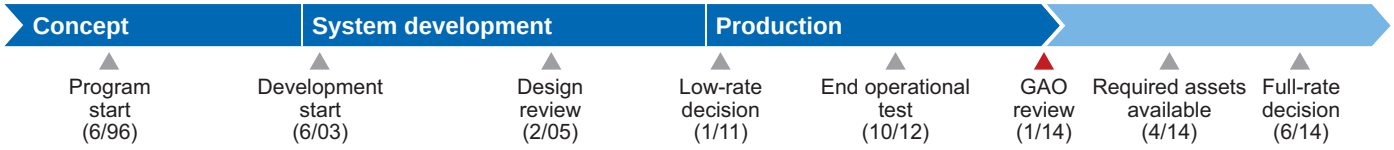
While the IAMD program has released nearly all of its total expected drawings and held a system level design review in May 2012, software problems and the Army's decision to operationalize the 32nd Test Battalion could cause further schedule delays and add substantial costs. For example, as a result of software development problems associated with the integrated battle command system, the IAMD program realigned software deliveries with key test activities. The revised software plan was approved in April 2013, resulting in a program delay of four months. Failure to properly develop, test, and integrate software could result in delay of capabilities being fielded to the warfigther. Also, the operationalization of the Patriot Test Battalion removes over 50 percent of the resources for both the Patriot and IAMD test programs. The IAMD and Patriot programs are working with the Army's test group to consider several options to mitigate potential risks, including delaying all test activities until Patriot test activities are complete and conducting tests with fewer assets. Further, tests of a fully integrated system-level prototype are not expected to begin until February 2014, over 20 months after design review.

Other Program Issues

IAMD's development costs have risen by about 48 percent, or over $717 million, since beginning development and may increase further. The Army restructured the program in 2011 to incorporate the Patriot launchers and radars directly on the integrated fire control network and to increase the number of units procured from 285 to 431 to account for adjustments to the battalion force structure and accelerating the fielding of capabilities. However, overall procurement costs have decreased by $194 million. According to program officials, increasing the number of units will provide for a common command and control at all organizational levels. Program officials estimate the size of the software development effort at over 6.6 million lines of code—a 37 percent increase over the estimate at development start. In addition, about 63 percent of this code will be newly developed code or auto-generated code which requires less effort to develop than newly developed or modified code.

Program Office Comments

In commenting on a draft of this assessment, the program office noted that since the software replan in early 2013, deliveries of software have been on schedule allowing for successful demonstration of the IAMD hardware/software architecture in late 2013 to the user. This demonstration also served as risk mitigation for early integration leading up to the developmental test program and limited user test in fiscal year 2014 and fiscal year 2015. Active risk plans are in place to manage program risks and the program office continues to work with other programs which IAMD is dependent on to ensure technical and programmatic risks are managed properly across programs. The loss of the test battalion will potentially result in some changes to the IAMD test program, but those changes are actively being worked with all stakeholders. Currently, it does not appear this resource challenge will affect IAMD's schedule. All program changes depicted in this report are captured in appropriate acquisition decision memorandums and the program's acquisition program baseline. The program office also provided technical comments which were incorporated where deemed appropriate.

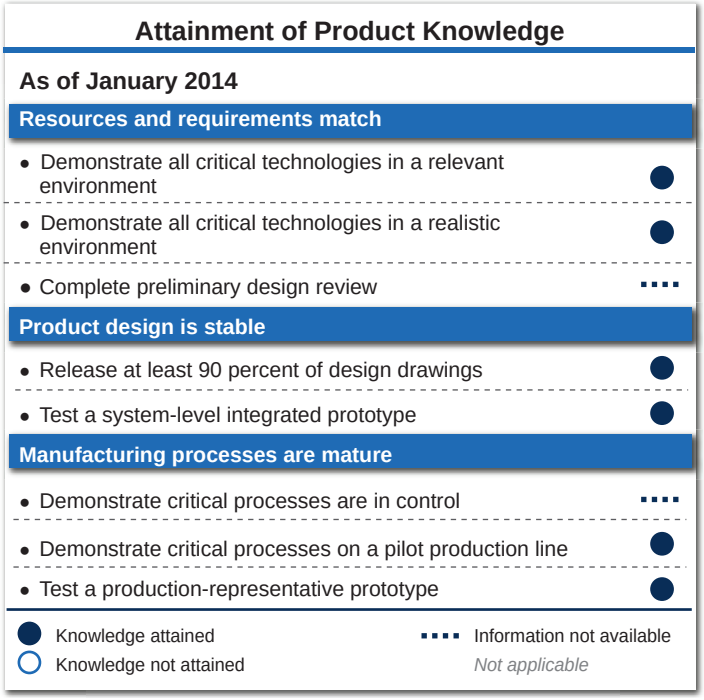


4120 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Joint Air-to-Surface Standoff Missile Extended Range (JASSM-ER)

The Air Force's JASSM-ER program plans to field a next-generation cruise missile capable of destroying the enemy's war-sustaining capability from outside its air defenses. JASSM-ER missiles are low-observable, subsonic, and have a range of greater than 500 miles. They provide both fighter and bomber crews the ability to strike heavily defended targets early in a campaign. JASSM-ER is a follow-on program to the JASSM baseline program. The two missiles' hardware is 70 percent common and their software is 95 percent common.

Source: U.S. Air Force.



Program Essentials

Prime contractor: Lockheed Martin
Program office: Eglin AFB, FL
Funding needed to complete:
- R&D: $25.1 million
- Procurement: $3,468.3 million
- Total funding: $3,493.4 million
- Procurement quantity: 2,847

Program Performance (fiscal year 2014 dollars in millions)

	As of 04/2011	Latest 08/2013	Percent change
Research and development cost	$286.8	$253.6	-11.6
Procurement cost	$3,636.3	$3,670.3	0.9
Total program cost	$3,923.1	$3,923.9	0.0
Program unit cost	$1.550	$1.318	-15.0
Total quantities	2,531	2,978	17.7
Acquisition cycle time (months)	NA	130	NA

The JASSM-ER program has experienced production issues that have resulted in delays to the full-rate production decision and may delay the deliveries required to provide for initial availability. The program has yet to accept any ER missile deliveries due to these production issues. Although significant, production issues are primarily limited to the new ER missile engine, as the rest of baseline and ER missile production has generally proceeded on schedule. Sequestration cuts for fiscal year 2013 have resulted in the Air Force deferring some missile purchases beyond fiscal year 2017, expanded obsolescence risk, and caused an increase in unfunded requirements.

4121 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

JASSM-ER Program

Technology Maturity

According to the program office, JASSM-ER's five critical technologies—the engine lube system, engine system, fuze, low observable features, and global positioning system—are mature and have been tested in a realistic environment using a production-representative test missile.

Design Maturity

JASSM-ER's design is currently stable and has been successfully demonstrated in operational tests. According to the program office, the number of configuration changes has decreased over time with only one significant design change in the last three years.

Production Maturity

The full-rate production decision for JASSM-ER has been delayed due to production issues which may also delay initial availability for the assets required. The program has yet to accept any ER missile deliveries because of these production issues.

The most significant of these issues is with the engine lubrication pump. Program officials stated they found that for some of the engine pumps produced, the internal metal components within the pump were chafing, releasing metal into the lubrication that could reduce performance. The program plans to change the component design and implement changes during production ramp up while relying on the current design and production line screening to remove faulty pumps in low-rate production. Also, the program experienced a supplier issue with the fuel control unit—an engine component that controls the fuel throttle, affecting missile speed and acceleration. They discovered the component supplier had used diluted glue which was weaker than what had been used during component qualification testing. Program officials stated all 30 of the first ER missiles produced are potentially affected and they placed a hold on accepting ER missile deliveries until an agreement is reached with Lockheed Martin on how to address those missiles.

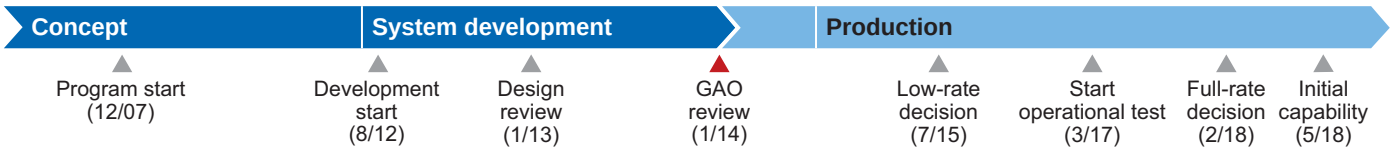
Aside from engine lube pump and fuel control unit issues, the program states production of the remaining 98 percent of ER subsystems and components have generally proceeded according to schedule. Production of the JASSM baseline variant has also largely been unaffected by ER production issues. Production of Lot 10 baseline missiles began in September 2013 with missile deliveries expected to begin in January 2014 while start of low-rate production of the second lot of ER missiles was delayed until January 2014.

Other Program Issues

According to the program office, sequestration cuts for fiscal year 2013 have resulted in the Air Force deferring some JASSM purchases to the out-years, increasing obsolescence risk, and increasing unfunded requirements. Prior to sequestration cuts, the program planned to reach its economic order quantity of 360 missiles per year in fiscal year 2016 but now plans to purchase missiles at the minimum sustainment rate for the foreseeable future. The program has some obsolescence issues that are not funded because of sequestration cuts, according to the program, which could lead to production gaps. Also, the program maintains sequestration cuts have resulted in unfunded requirements, such as warranties for upcoming missile purchases, production tooling for full rate production ramp up, and some evaluation testing.

Program Office Comments

In commenting on a draft of this assessment, the Air Force provided technical comments, which were incorporated where deemed appropriate.

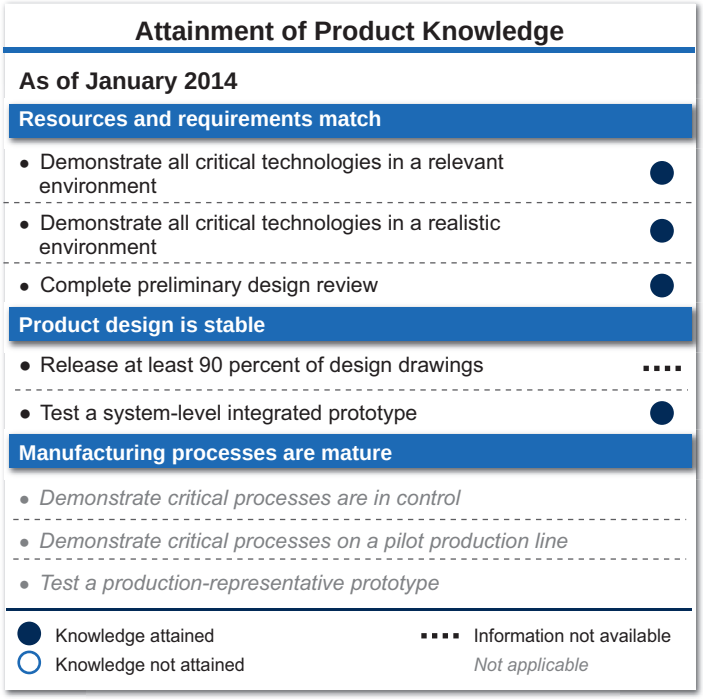


4122 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Joint Light Tactical Vehicle (JLTV)

The Army and Marine Corps' JLTV is a family of vehicles being developed to replace the High Mobility Multipurpose Wheeled Vehicle (HMMWV) for some missions. The JLTV is expected to provide better protection for passengers against current and future battlefield threats, increased payload capacity, and improved automotive performance over the up-armored HMMWV; it must also be transportable. Two- and four- seat variants are planned with multiple mission configurations.

Sources: JPO JLTV EMD Industry Contractors (AM General, Oshkosh Corp. & Lockheed Martin)



Program Essentials

Prime contractor: AM General, Lockheed Martin, Oshkosh
Program office: Harrison Township, MI
Funding needed to complete:
R&D: $377.3 million
Procurement: $22,651.7 million
Total funding: $23,046.9 million
Procurement quantity: 54,599

Program Performance (fiscal year 2014 dollars in millions)

	As of 10/2012	Latest 07/2013	Percent change
Research and development cost	$1,001.1	$981.0	-2.0
Procurement cost	$22,661.3	$22,651.7	0.0
Total program cost	$23,699.8	$23,650.5	-0.2
Program unit cost	$0.433	$0.432	-0.2
Total quantities	54,730	54,730	0.0
Acquisition cycle time (months)	125	125	0.0

JLTV's two critical technologies have been demonstrated in a realistic environment on prototype vehicles, according to program officials. In lieu of a critical design review, the program held a design understanding review in January 2013, and according to program documents, confirmed that all three contractors had more than 90 percent of design files under configuration control. A recent manufacturing readiness assessment concluded that all three vendors were on track to achieve production maturity by low-rate initial production. All variants are envisioned to meet transportability requirements, and testing is ongoing to confirm this with production representative versions

4123 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

JLTV Program

Technology Maturity

According to the program office, its critical technologies—underbelly protection armor and side-kit armor—are fully mature. According to program officials, ballistic testing conducted since November 2012—including armor samples, vehicle cabs, and chassis—confirmed this, and both technologies have been demonstrated in fielded systems. However, integrating the technologies to meet all system-level requirements for transportability, protection, and mobility could prove challenging,

Design Maturity

The program office did not hold a formal critical design review for JLTV, but conducted design understanding reviews with contractors between December 2012 and January 2013. According to program officials, these reviews were at a level of detail similar to a critical design review and were held to support the requirement for mature vehicle designs at the time of contract award for system development. At the time of these reviews, all long-lead and critical designs had been completed and all three contractors had more than 90 percent of the design files under configuration control. The Office of the Deputy Assistant Secretary of Defense (Systems Engineering) affirmed that the exit criteria for system development had been satisfied. According to program documentation, contractors will maintain responsibility for configuration control and will inform the government of changes. The government will assume control of the design after the planned award of one low-rate initial production contract in 2015.

Production Maturity

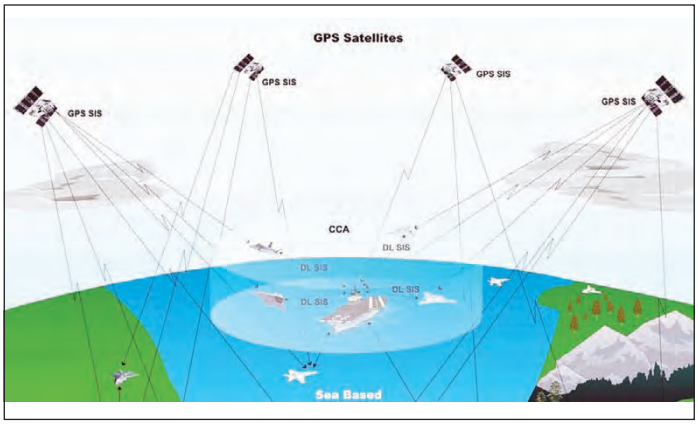
The Army does not intend to use process capability index data to assess production maturity, as recommended by our best practices. Instead, it intends to use other metrics, such as predicted assembly times and feasibility studies to assess production maturity by the production readiness review, scheduled for September 2014. The program recently conducted a manufacturing readiness assessment with all three vendors to evaluate manufacturing readiness, including a self-assessment of manufacturing readiness levels by the vendors. The program office believes all three vendors are on track to be production capable by low-rate initial production contract award in 2015. Production processes are not expected to be fully in control as program officials noted that tooling will not be fully documented until this point due to the large capital investment required.

Other Program Issues

On the basis of the knowledge gained from the technology development phase, the Army and Marine Corps concluded the JLTV could not meet requirements for both protection levels and transportability because of weight and relaxed the requirement to transport the vehicle by helicopter at high altitude and at certain temperatures. Program officials acknowledge some risk still exists in vehicles achieving relaxed weight requirements, but the prototype weigh-ins were on track, thus diminishing risk. Prototype vehicle testing will continue through October 2014, and the results will be used to determine whether the vehicles meet system requirements. Army officials recognize that the test schedule is compressed, and that slips in the limited user test could result in a slip of the program's production decision planned for July 2015. However, program officials believe that the results of testing will be available in sufficient time.

At the end of the system development phase, a low-rate initial production contract will be awarded to a single source. The program office will seek approval to limit competition to the three current vendors, but if not approved will revert to a full and open competition strategy. The program office does not believe there are any viable sources for JLTV production other than the three current vendors.

Finally, the Army plans to begin procuring JLTV while simultaneously procuring the Armored Multi-Purpose Vehicle. The simultaneous procurement of these programs is expected to continue for a decade or more.



Program Office Comments

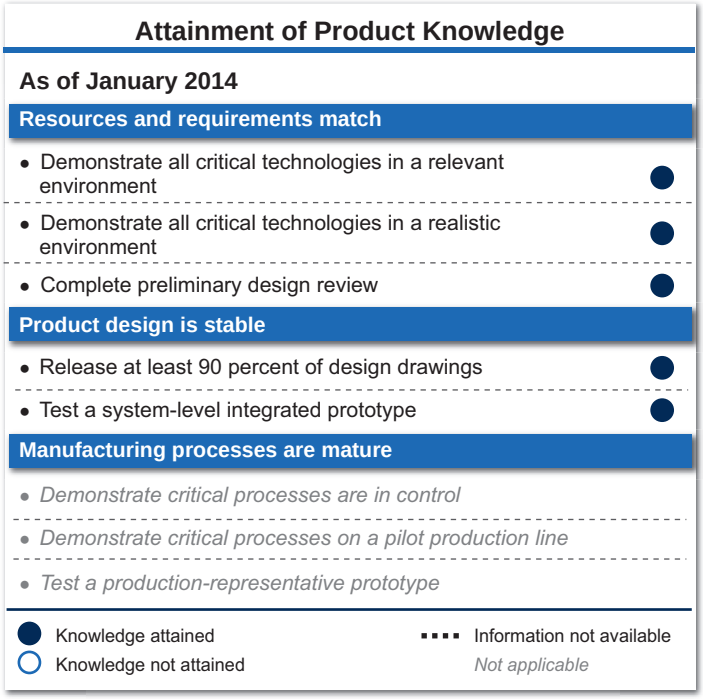
In commenting on a draft of this assessment, the program office provided technical comments, which were incorporated where deemed appropriate.

4124 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Joint Precision Approach and Landing System Increment 1A (JPALS Inc 1A)

JPALS Increment 1 is a Navy-led program to develop a GPS-based aircraft landing system to replace current radar-based systems on its ships. It is designed to provide reliable precision approach and landing capability in adverse environmental conditions and improved interoperability. Increment 1A is the ship-based system and increment 1B will integrate JPALS with sea-based aircraft. Both are needed to provide the full capability. We assessed increment 1A and made comments on increments 1B, 2, and other follow-on efforts.

Source: U.S. Navy.



Program Essentials

Prime contractor: Raytheon
Program office: Lexington Park, MD
Funding needed to complete:
- R&D: $115.8 million
- Procurement: $257.7 million
- Total funding: $373.5 million
- Procurement quantity: 27

Program Performance (fiscal year 2014 dollars in millions)

	As of 07/2008	Latest 09/2013	Percent change
Research and development cost	$833.1	$859.3	3.1
Procurement cost	$224.3	$257.7	14.9
Total program cost	$1,064.7	$1,124.2	5.6
Program unit cost	$28.775	$30.385	5.6
Total quantities	37	37	0.0
Acquisition cycle time (months)	75	96	28.0

JPALS Increment 1A's two critical technologies are mature and have been demonstrated in a realistic environment. Program officials reported completing baseline software development as of April 2012. The program began system-level development testing in July 2012 and sea-based testing in December 2012. The program completed 108 integrated flight tests with no major anomalies reported. Increment 1A's production decision scheduled for November 2013 was cancelled due to budget reductions, with a new date to be determined. Ship availability delays for installation and procurement changes resulted in schedule and cost breaches, respectively, of thresholds in the program's baseline. Increment 1B is scheduled to start system development in 2015. Lead responsibility for Increment 2, land-based JPALS, transferred from the Air Force to the Navy beginning in fiscal year 2014.

4125 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

JPALS Inc 1A Program

Technology Maturity

JPALS Increment 1A's two critical technologies are mature and have been demonstrated in a realistic environment. Program officials reported demonstrating the technologies during sea-based flight testing in 2013. JPALS functionality is primarily software-based, and the program reported that its software development and integration effort was complete as of April 2012. The program will continue developmental testing, with operational testing planned to begin in 2016.

Design Maturity

The JPALS program held its critical design review in December 2010 and released all of its expected design drawings to manufacturing at that time. The JPALS design is currently stable, and the program began system-level development testing of a prototype in July 2012 to show that it will perform as expected. Sea-based testing began in December 2012 and program officials reported completing 108 integrated flight tests as of July 2013, with no major anomalies identified. Shore-based auto-landing demonstrations began in October 2013, and program officials reported completing 70 ship-based auto-landing demonstrations as of November 2013.

Production Maturity

According to JPALS program officials, the program has not identified any critical manufacturing processes and the system's hardware is comprised primarily of off-the-shelf components. The program has accepted delivery of all eight of its engineering development models, seven of which are production representative.

Other Program Issues

The program's production decision, scheduled for November 2013, was cancelled and a new date has yet to be determined. Program officials stated that budget reductions due to sequestration eliminated funding for the low-rate initial production contract. They noted that a new date will not be scheduled until the Navy resolves this funding issue. The program previously delayed the production decision from May 2013 to November 2013 because the aircraft carrier needed to conduct ship-based integrated testing was not available for installation. As a result, the program reported a schedule breach of the acquisition program baseline.The program also extended planned production to avoid acquiring systems earlier than needed and moved the purchase of one unit from development to procurement. These changes increased procurement costs and resulted in a cost breach of a threshold set in the acquisition baseline.

System development for JPALS Increment 1B—which will integrate JPALS with sea-based aircraft—is scheduled for 2015. Program officials stated that increment 1B will be developed to provide JPALS functionality in a packaged way that allows for integration with any aircraft rather than tailoring efforts to each individual platform. Increment 2 is the land-based version of JPALS and system development is scheduled for 2015. Beginning with fiscal year 2014, lead service responsibility for JPALS Increment 2 transferred from the Air Force to the Navy.

Program officials stated that the recently conducted successful auto-land demonstrations may allow for the incorporation of capabilities planned for future increments. Incorporating auto-land and unmanned aerial vehicle capabilities into increments 1A and 1B will provide enabling technology for the Navy's future ship classes and the Unmanned Carrier-Launched Surveillance and Strike program for which JPALS was selected as the primary landing system.

Program Office Comments

In commenting on a draft of this assessment, the JPALS program office noted that it concurred with our review and that flight testing was highly successful and the system performed as intended with no significant design or performance issues identified to date. The program is working aggressively with the Navy and the Office of Secretary of Defense to resolve the cost and schedule breaches, and anticipates corrective actions will be incorporated in the fiscal year 2015 President's budget submission. The progam office also provided technical comments, which were incorporated where deemed appropriate.

- Procurement: $6,706.3 million
- Total funding: $6,737.7 million
- Procurement quantity: 236,240

Program Performance (fiscal year 2014 dollars in millions)

	As of 05/2004	Latest 09/2013	Percent change
Research and development cost	$572.9	$1,255.8	119.2
Procurement cost	$9,984.0	$7,680.2	-23.1
Total program cost	$10,556.9	$8,935.9	-15.4
Program unit cost	$0.032	$0.033	2.6
Total quantities	328,674	271,202	-17.5
Acquisition cycle time (months)	85	112	31.8

The JTRS HMS program continues to conduct operational testing on both the Rifleman and Manpack variants and has demonstrated full maturity of all technologies, but has not demonstrated its production processes. Program officials have taken steps to address the Manpack reliability shortfalls identified during operational testing in May 2012 and plan to demonstrate the radio's capabilities during follow-on testing in May 2014. Full-rate production decisions for both variants have been delayed to fiscal year 2015 because of a change in the program's acquisition strategy to allow new vendors to compete for the contracts. In December 2013, the program received approval to increase the low-rate initial production quantity for the Manpack radio. The program is working with the Army to manage capability gaps resulting from both radios' full-rate production delays.

JTRS HMS Program

Technology Maturity

According to a program official, JTRS HMS has fully demonstrated the maturity of all its critical technologies for both the Rifleman and Manpack radios. The program has conducted operational testing on both variants for over four years, and plans to conduct additional testing in fiscal year 2014.

Design Maturity

According to program officials, the designs of both variants are stable, but reliability issues for the Manpack radio could require design modifications. Following operational testing in May 2012, DOD test officials reported that the Manpack was not operationally effective or suitable because it failed to demonstrate a reliability requirement. Program officials said they have taken steps to address the Manpack's reliability shortfalls and plan to demonstrate all remaining capabilities during follow-on testing in May 2014.

Production Maturity

According to JTRS HMS officials, the program's manufacturing readiness is at a level consistent with DOD guidance, but not yet at a level that demonstrates that its critical manufacturing processes are in control.

Other Program Issues

Both variants of JTRS HMS have experienced additional schedule slips since last year's assessment. The program revised its acquisition strategy following an Office of the Secretary of Defense directive that JTRS HMS conduct full and open competition for the full-rate contracts for both variants. As a result, the program office expects the full-rate production decisions for the Rifleman and Manpack radios to slip from the second half of fiscal year 2013 to March and September 2015, respectively. Prior to the full-rate production decisions, the program must solicit proposals from new vendors and, according to program officials, will likely award new contracts and test new radios. The Army would have to demonstrate that these new radios meet the Rifleman and Manpack requirements in an operationally-realistic environment. This delay puts the program nearly three years behind the originally scheduled full-rate production decisions for the Rifleman radio in May 2012 and the Manpack radio in December 2012. The program manager said he is working with Army operations and resource management staff to manage capability gaps resulting from both radios' full-rate production delays. They will establish deployment quantities and locations for the HMS radios procured through low-rate initial production to meet the Army's immediate needs. The program received approval for an additional lot of 1,500 Manpack radios in December 2013, but has not received authorization to increase the low-rate initial production quantity for the Rifleman radio over the current level set by the Office of the Secretary of Defense in July 2012.

Additionally, demonstrating the Manpack with the MUOS antenna and waveform remains a technical risk for the program. The JTRS HMS program is currently scheduled to field the MUOS-capable Manpack radios in 2014, but officials stated that they will wait to demonstrate the Manpack with the MUOS antenna and waveform until after the MUOS program successfully completes its own operational testing, which is scheduled for June 2014.

Program Office Comments

In commenting on a draft of this assessment, program officials noted that in 2012, HMS early operational tests were conducted on low-rate initial production variants of the HMS Manpack radio. Since this test, numerous corrected deficiencies have been implemented, including production improvements and extended environmental stress screening, significant improvement has been documented in follow-on performance verification testing and will be formally demonstrated at the Network Integration Evaluation 14.2 in May 2014. HMS Rifleman and Manpack radios have been successfully fielded and are in use by operational units in support of global operations. To meet operational needs, in December 2013, the Office of the Secretary of Defense approved an additional low-rate initial production allotment of HMS Manpack radios, while also indicating support for a multi-vendor, multi-award construct for HMS full rate production.

KC-46 Tanker Modernization Program (KC-46)

The Air Force's KC-46 program plans to convert an aircraft designed for commercial use into an aerial refueling tanker in order to refuel Air Force, Navy, Marine Corps, and allied aircraft. The program is the first of three planned phases to replace the Air Force's aging fleet of KC-135 aerial refueling tankers. The KC-46 has been designed to improve on the KC-135's refueling capacity, efficiency, capabilities for cargo and aeromedical evacuation, and to integrate defensive systems.

Total quantities	179	179	0.0
Acquisition cycle time (months)	78	78	0.0

The program held its critical design review in July 2013 with its critical technologies nearing full maturity and its design stable but not demonstrated. To reduce risk and improve schedule, Boeing decided to develop situational awareness software internally prior to the critical design review. This resulted in replacing one of the program's critical technologies and re-using software code. Boeing is currently manufacturing the four development aircraft, but test boom production has been delayed by almost a year due to design changes and late parts. The program has demonstrated that it can produce the required military subsystems in a production representative environment, but these processes will not be in control by the low-rate production decision. The Air Force and Boeing are working through software and hardware integration and flight test risks.

4129 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

KC-46 Program

Technology Maturity

The KC-46 entered system development with its critical technologies—a three-dimensional display to monitor and enable aerial refueling activities and a software module designed to increase situational awareness—nearing full maturity, but not yet demonstrated in a realistic environment. In March 2013, almost four months before the program's critical design review, Boeing decided to develop the situational awareness software internally. Boeing's version of this development effort replaced the prior software modules with a new one. The new software module is nearing full maturity, but has not yet been demonstrated in a realistic environment. To reduce risk and improve schedule, Boeing re-used some of the situational awareness software code from prior programs. The program plans to fully mature its critical technologies prior to its low-rate production decision.

Design Maturity

The program held its critical design review in July 2013 with over 90 percent of its design drawings releasable, but before fully maturing its technologies and testing an aircraft that integrates the military sub-systems. The program will not begin testing an aircraft that integrates military sub-systems until January 2015, 18 months after its critical design review. Best practices call for completing a full system-level prototype demonstration by the critical design review in order to show that the design is capable of meeting performance requirements.

Production Maturity

Boeing has begun production of the four development aircraft, and is also manufacturing a test refueling boom and a boom for the first development aircraft. Test refueling boom production has been delayed by almost a year due to design changes and late parts deliveries. Boeing officials said the test refueling boom is a risk reduction effort and lessons learned will be applied to future boom builds. The program reported that it is primarily using manufacturing readiness levels to assess manufacturing risk. As of July 2013, the program demonstrated that it is capable of producing the applicable military subsystems, such as several aerial refueling and defensive subsystems, in a production representative environment. The low-rate initial production decision is currently scheduled for August 2015, but the program will not have its production processes for military subsystems in control at that time as recommended by best practices.

Other Program Issues

The Air Force has identified software and hardware integration and the aggressive nature of the KC-46 flight test schedule as top program risks. While most software and hardware integration has progressed according to plan, these efforts have largely addressed commercial rather than military unique components to date, and some aerial refueling and avionics software has not been delivered on time. The flight test pace is more aggressive than other military aircraft development programs, and Boeing's test approach requires a significant amount of coordination among key stakeholders. The program office and Boeing are working together to mitigate these risks by, for example, conducting dry runs prior to flight testing.

Program Office Comments

In commenting on a draft of this assessment, the program stated they mitigated risk by negotiating the competitive fixed-price incentive development contract with firm-fixed and not-to exceed pricing for production. The program noted that about 50 percent of the development work has been completed thus far and Boeing has met or exceeded all contractual requirements. The program is closely tracking software as a risk, however, it does not believe there are significant software-related issues at this time. The program further stated that it plans to mitigate the risk posed by concurrency by ensuring that adequate testing is completed prior to the production decision. In addition, Boeing's contract requires it to incorporate fixes into production aircraft at no additional cost. DOD and the Air Force also provided technical comments, which were incorporated as appropriate.

LHA 6 *America* Class Amphibious Assault Ship (LHA 6)

The Navy's LHA 6 class will replace the LHA 1 *Tarawa* class amphibious assault ships. LHA 6 class is based on the fielded LHD 8 and consists of three ships. The ships will feature enhanced aviation capabilities and are designed to support Marine Corps assets in an expeditionary strike group. LHA 6 construction began in December 2008 and ship delivery is expected in March 2014. LHA 7 construction began in July 2013 and delivery is expected in December 2018. The Navy intends to award the construction contract for LHA 8 in fiscal year 2017.

Total quantities	1	3	200.0
Acquisition cycle time (months)	146	177	21.2

LHA 6 began construction in December 2008 with mature technologies and a design that was only 65 percent complete. After a 19 month delay, the Navy expects delivery will occur in March 2014. LHA 6 will also incur an estimated $42.4 million in cost growth due to postdelivery rework of the ship's deck to cope with Joint Strike Fighter exhaust and downwash. Construction of LHA 7 (which largely shares the LHA 6 design) began in July 2013 and the program office believes that the issues that led to cost increases and schedule delays on LHA 6 have been largely resolved and are unlikely to cause problems for LHA 7. Design changes to LHA 8 are more significant and include the addition of a well deck. The Navy plans to competitively award a construction contract for LHA 8 and has awarded contracts with two shipyards to assist with early design work.

4131 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

LHA 6 Program

Technology, Design, and Production Maturity

All LHA critical technologies were mature when the program awarded its construction contract in June 2007. Although not considered critical technologies, the program has identified an additional six key subsystems necessary to achieve capabilities. Five of these subsystems are mature. The sixth, the Joint Precision Approach and Landing System, is still in development, but LHA 6 can use backup aviation control systems to meet requirements. There are no new critical technologies expected for LHA 7 or LHA 8, but requirements for LHA 8 are still in development.

In January 2014, the Navy and the shipbuilder conducted acceptance trials on LHA 6 and Navy officials anticipate ship delivery will occur in March 2014, 19 months later than the contracted delivery date. At the time of acceptance trials, the LHA 6 design was at least 99 percent complete and construction was over 97 percent complete. LHA 6 began construction in December 2008 with only 65 percent of its design complete, and subsequent design quality issues have caused more design changes than anticipated and higher levels of rework. Following the delivery of LHA 6, the Navy will spend an estimated $42.4 million to reconfigure the ship's flight deck to cope with exhaust and downwash from the Joint Strike Fighter.

Construction of LHA 7 (which largely shares the same design as LHA 6) began in July 2013 and flight deck modifications due to JSF are still being incorporated into the design. Officials, however, do not believe that this will interfere with the ship's construction. Other design changes to LHA 7 include a new firefighting system and updates to the radar and the command, control, communications, computers, and intelligence systems. Design changes to LHA 8 will be more significant as the Navy will incorporate a well deck that can accommodate two landing craft. Program officials note that the new design also allows for better maintenance of aviation capabilities. The program may also incorporate a flexible infrastructure—which would allow compartments to be reconfigured to meet changing mission needs with less rework—into some low risk areas of the LHA 8 design should the Navy determine that it results in lifecycle cost savings.

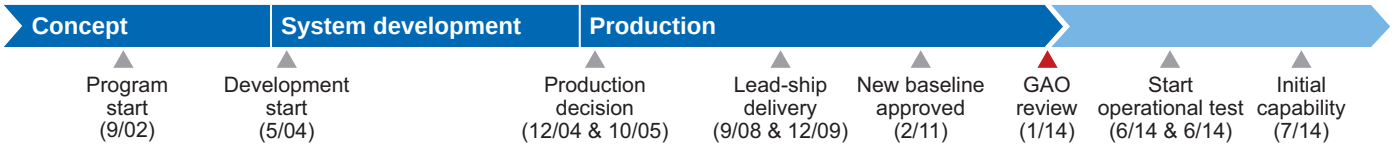
Other Program Issues

Program officials believe that as a result of increasing the number of design drawing reviews and ensuring additional lead time for material orders on LHA 7, the program will not experience the high level of rework that led to cost growth and schedule delays during construction of LHA 6. In order to improve quality and shipyard performance on LHA 7, the Navy included contract incentives of up to $41 million; although officials note that it is too soon to determine whether the incentives are effective at keeping rework rates low.

The Navy intends to competitively award a construction contract for LHA 8, and in November 2012 awarded early industry involvement contracts to two shipbuilding contractors that it determined are capable of building the ship without major recapitalization. The contracts allow the shipbuilders to participate in early stage design work and investigate opportunities for potential cost reductions, and were recently modified to extend the period of performance past the past the original April 2014 contract expiration date.

Program Office Comments

In commenting on a draft of this assessment, the program program office stated that based on the success of LHA 6's acceptance trials, the Navy's independent assessor—the Board of Inspection and Survey—recommended that the Navy accept delivery of the ship. The extension of the periods of performance of the early industry involvement contracts for LHA 8 efforts will allow the joint industry/government team to continue working on identifying innovative ways to reduce the projected cost of the ship. The program office also provided technical comments, which were incorporated as appropriate.



4132 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Littoral Combat Ship (LCS)

The Navy's LCS is designed to perform mine countermeasures, antisubmarine warfare, and surface warfare missions. It consists of the ship itself, or seaframe, and the mission packages it deploys. The Navy bought the first four seaframes in two unique designs—one based on a steel semi-planing monohull (Freedom variant) and the other based on an aluminum trimaran hull (Independence variant)—and subsequently awarded a contract for a block buy of up to 10 ships to both contractors. We assessed both seaframe designs

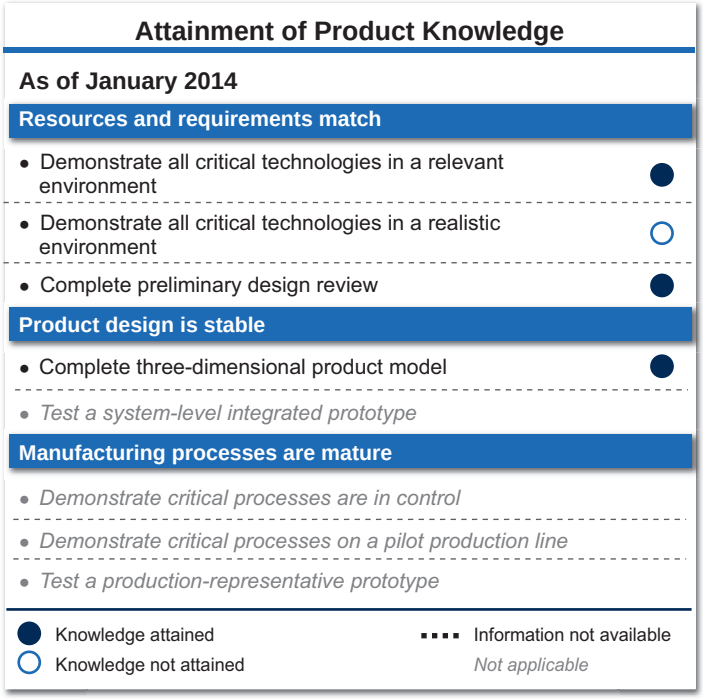
Program Essentials



Prime contractor: Austal USA, Lockheed Martin
Program office: Washington Navy Yard, DC
Funding needed to complete:
R&D: $704.1 million
Procurement: $18,775.1 million
Total funding: $19,631.6 million
Procurement quantity: 36

Program Performance (fiscal year 2014 dollars in millions)

	As of 05/2004	Latest 12/2012	Percent change
Research and development cost	$932.9	$3,596.3	285.5
Procurement cost	$496.0	$26,214.6	5,185.2
Total program cost	$1,428.9	$30,027.0	2,001.4
Program unit cost	$357.225	$577.442	61.6
Total quantities	4	52	1,200.0
Acquisition cycle time (months)	41	122	197.6

Cost data are for the seaframe only. Research and development funding includes detail design and construction of two ships. DOD recently announced plans to reduce total seaframe quantities to 32.

The LCS seaframe program has demonstrated the maturity of 16 of its 18 critical technologies and continues to make design and production process changes. Additional design changes have been endorsed by the LCS Council for fiscal year 2015: bridge wings and a seven-meter rigid hull inflatable boat for the Independence variant and stronger stern ramp for the Freedom variant. The Navy accepted delivery of LCS 4 in September 2013, a delay of 6 months, and is in steady production with 12 hulls under contract and/or construction. The next block-buy is scheduled for fiscal year 2016, when 24 seaframes will already be delivered, constructed, or under contract.

4133 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

LCS Program

Technology Maturity

Sixteen of the 18 critical technologies for both LCS designs are mature and have been demonstrated in a realistic environment. The two remaining technologies—LCS 1's overhead launch and retrieval system and LCS 2's aluminum structure are nearing maturity—according to our best practice standards. Though program officials believe that LCS 2's aluminum structure hull is mature as the ship is operational, there are still unknowns related to the hull structure. As a result, full maturity will not be demonstrated until the completion of shock and survivability trials to validate survivability and the ship's ability to achieve a 20-year service life. These tests are not expected to begin until August 2015.

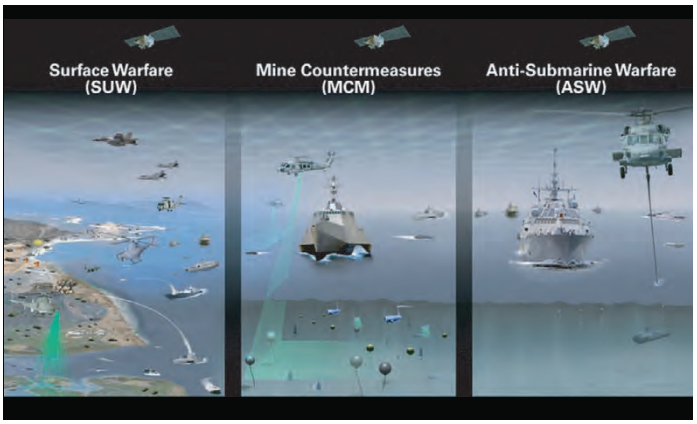
Design and Production Maturity

The Navy started construction of LCS 1 and 2 without a stable design and has had to incorporate design changes on follow-on seaframes. LCS 1 and LCS 2 are still undergoing testing, and the Navy is incorporating design fixes for identified deficiencies into the designs of follow-on ships. In addition, a series of additional design changes for both variants have been approved by the LCS Council for fiscal year 2015; including bridge wings and a seven-meter rigid hull inflatable boat for the Independence variant and stronger stern ramp for the Freedom variant. LCS 4 experienced delays and was delivered six months after its expected contract delivery date of March 2013. LCS 5 through LCS 12 are currently in various stages of construction. The Navy is concerned about both contractors' ability to meet construction schedules without impacting follow-on hulls.

LCS 1 completed a ten-month deployment to the western pacific in December 2013 where it operated out of Singapore. During this deployment it encountered two significant engineering issues that significantly curtailed its ability to get underway: the lubrication cooling system ruptured and the ship service diesel engine generator had reliability issues. In addition to these engineering issues, LCS 1 had a number of combat system and other material failures; including radar underperformance and the combat system unexpectedly rebooting during operations.

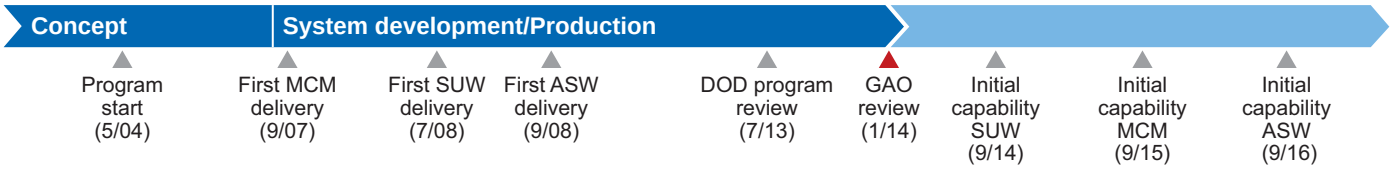
Other Program Issues

The Navy added 20 permanent berths to LCS 1 to support additional manning for its deployment to Singapore in 2013. In May 2013, the Navy determined that additional permanent accommodations for a total crew size of 98 should be incorporated in all LCS class ships. The LCS program executive office has been directed to add these permanent accommodations through either forward -or back-fitting the ships. Although the habitability modification installed on LCS 1 in support of its deployment did not include the addition of increased storage and water supplies, the forward fit installs will address the required services and auxiliary system modifications associated with the installation of the additional berthing. Following LCS 1's 2013 deployment, the Navy will evaluate lessons learned and future manning options. The Navy expects to complete this evaluation in fiscal year 2014 and incorporate any proposed manning changes beginning in fiscal year 2015 ahead of the next block buy decision in 2016, when 24 seaframes will already be delivered, constructed, or under contract.



Program Office Comments

In commenting on a draft of this assessment, the program office noted that LCS 4 showed significant improvement from LCS 2 in level of completeness and number of high priority trial cards deficiencies at delivery. Twelve block buy ships are funded on the block buy contract and are in pre-production or construction, following thorough production readiness reviews. LCS 5 and 6 launched in December 2013. LCS 1 deployment successfully validated major portions of the LCS concept of operations for crew rotation and contracted overseas maintenance. Ship service diesel generator and seawater cooler reliability issues were satisfactorily addressed during deployment. Engineering changes have been incorporated to prevent and mitigate those issues in the future. Material failures of the radar were a result of a procedural error causing the system to reboot, however the radar performed to design specifications. The program office also provided technical comments, which were incorporated where deemed appropriate.



4134 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Littoral Combat Ship - Mission Packages (LCS MP)

The Navy's Littoral Combat Ship (LCS) will provide mine countermeasures (MCM), surface warfare (SUW), and antisubmarine warfare (ASW) capability using mission packages. Packages include weapons and sensors launched and recovered from LCS seaframes and operated from MH-60 helicopters and unmanned vehicles. The Navy plans to deliver capability to the fleet in increments. We are assessing the Navy's progress in achieving full baseline performance capability, including all planned increments needed to achieve this capability for each package.

Program Essentials

Prime contractor: Northrop Grumman Corporation M&TS
Program office: Washington Navy Yard Washington, DC
Funding needed to complete:
R&D: $1,647.1 million
Procurement: $3,656.4 million
Total funding: $5,334.9 million
Procurement quantity: 51

Program Performance (fiscal year 2014 dollars in millions)

	As of 08/2007	Latest 01/2014	Percent change
Research and development cost	$517.2	$3,103.4	NA
Procurement cost	$3,427.8	$4,108.7	19.9
Total program cost	$3,954.7	$7,243.5	NA
Program unit cost	$61.792	$113.180	NA
Total quantities	64	64	0.0
Acquisition cycle time (months)	NA	NA	NA

The 2007 RDT&E cost estimate does not reflect full program costs and cost growth is not applicable. Current estimate does not include $3.6 billion of procurement money for replacement and other items.

In November 2013, DOD approved the baseline for the LCS Mission Packages program and previously, in October 2012, transferred decision authority to the Navy which approved the programs milestone B decision. The Navy held the milestone B event, which normally indicates development start, in January 2014 but has been developing the packages since 2004 and has delivered eight partial packages. As a part of this event, the Navy produced the first full lifecycle cost estimate. The program's acquisition cost is now $7.24 billion, an increase of $3.29 billion based upon its 2007 estimate, which did not include full development costs. The Navy plans to deliver mission package capabilities in increments, the MCM and SUW mission packages are not currently expected to field their baseline performance capability until the Navy has purchased 32 and takes delivery of 24 seaframes.

4135 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

LCS Packages Program

Mine Countermeasures (MCM)

The Navy has accepted four packages without demonstrating that they meet requirements and plans to accept two more in fiscal 2014. The package will be fielded in four increments: the first intends to remove sailors from the minefield and improve mine detection, classification, and destruction over legacy vessels. Although DOD states that all systems in increment one are fully mature, developmental testing has shown performance problems that led to changes in planned tactics, removal of systems, and lowered testing requirements. For example, corrections to the mine-hunting sonar's reliability have yet to be validated in operational testing, and two systems, intended to sweep for and neutralize mines, had to be removed for safety and performance issues. Also, the Navy now requires multiple searches to identify mines, adding time to the process, and has lowered increment one testing requirements for mine clearance rates. If operational testing proves successful, this package will not be able to replace all legacy capability until increment three completion in fiscal 2017.

Surface Warfare (SUW)

The Navy has taken delivery of four packages, each comprised of two 30 millimeter guns, as well as a rigid hull inflatable boat prototype, boarding gear, and armed helicopters. Following the cancellation of the non-line-of-sight launch system, the Navy planned to field the Griffin missile in 2015 as an initial capability. However, program officials stated that the Navy is rethinking this and a solution is not yet known.

Antisubmarine Warfare (ASW)

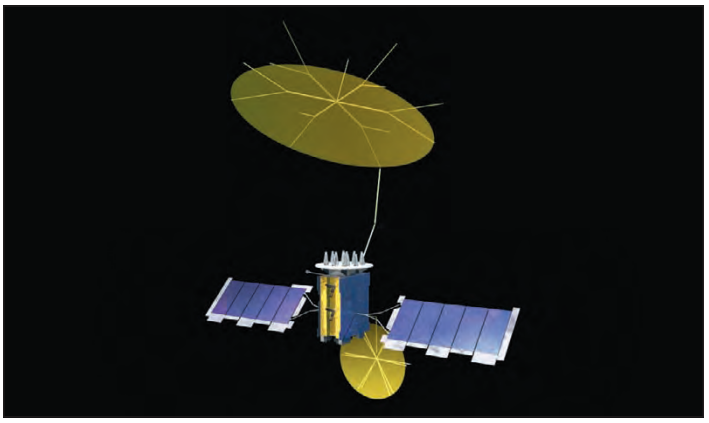
The Navy restarted development of an ASW package with new requirements as the initial package was not going to deliver enough capability over legacy assets. The Navy is assessing a replacement, with initial delivery planned in 2016, that is expected to include, among other technologies, a variable-depth sonar—which, according to officials, performed well in initial tests—and a towed array. The maturity of these technologies has not yet been independently assessed.

Other Program Issues

The Navy held a preliminary design review in 2004, but the packages have substantively changed. The program held a milestone B event in January 2014 with an estimated acquisition cost of $7.24 billion. Tests for increment one and two of the SUW and increment one of the MCM package are scheduled for fiscal 2014 and 2015 respectively. These assessments evaluate progress in achieving baseline performance capability, which includes all planned increments for each package. The Navy plans to purchase 32 LCS seaframes and take delivery of at least 24 by the time the baseline performance capabilities of the MCM and SUW packages are proven and fielded.

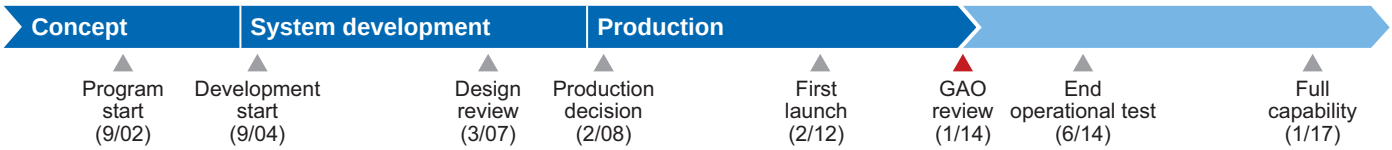
Program Office Comments

The Navy states that our assessment of program cost growth incorrectly compares the acquisition program baseline against a fiscal 2008 baseline, which does not reflect the total acquisition. Further, the Navy states that this assessment disregards near term operational requirements as the data presented indicates that the program should be delayed. The Navy also states that our assertion of excessive program risk, due to concurrency, is unfounded because developmental testing, combined with capability proven during early deployments, has significantly reduced technical risk. This is evidence, according to the Navy, that the LCS will successfully complete operational testing. Lastly, the current missile procurement was delayed due to sequestration; the Navy states that the program is on track to deliver a capability in late 2016.



GAO Response

In comparing the 2007 estimate with the acquisition program baseline, we used the Navy's 2007 data, which included full procurement costs but only five years of development cost. The Navy has acquired eight packages without proving capability through operational testing. In the absence of a defined increment-based approach for the full baseline capability to sequentially gain knowledge and meet these requirements, the Navy's acquisition approach is not in accordance with best practices or DOD guidance in place at the time of our review.



4136 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Mobile User Objective System (MUOS)

The Navy's MUOS, a satellite communication system, is expected to provide a worldwide, multiservice population of mobile and fixed-site terminal users with increased narrowband communications capacity and improved availability for small terminal users. MUOS will replace the Ultra High Frequency (UHF) Follow-On (UFO) satellite system currently in operation and provide interoperability with legacy terminals. MUOS consists of a network of satellites and an integrated ground network. We assessed both the space and ground segments.

Program Essentials

Prime contractor: Lockheed Martin Space Systems
Program office: San Diego, CA
Funding needed to complete:
- R&D: $176.9 million
- Procurement: $975.1 million
- Total funding: $1,152.0 million
- Procurement quantity: 1

Program Performance (fiscal year 2014 dollars in millions)

	As of 12/2004	Latest 09/2013	Percent change
Research and development cost	$3,836.4	$4,511.6	17.6
Procurement cost	$3,192.1	$2,867.4	-10.2
Total program cost	$7,069.1	$7,448.1	5.4
Program unit cost	$1,178.186	$1,241.345	5.4
Total quantities	6	6	0.0
Acquisition cycle time (months)	90	NA	NA

Latest acquisition cycle time could not be calculated because the most recent MUOS program baseline does not estimate dates for operational capability.

The MUOS program's critical technologies are mature, its design is stable, and according to the program office, its manufacturing process maturity has increased. The first satellite was launched in February 2012—26 months later than planned at development start—and the second satellite was launched in July 2013. Subsequent launches of MUOS satellites remain important due to the past operational failures of two UFO satellites and predicted end-of-life of on-orbit UFO satellites, one of which was taken off-line in November 2012. A remaining challenge is that users will not be able to utilize advanced MUOS capabilities in large part because of delays in the development, testing, and fielding of new user terminals. Current MUOS user terminal procurement and fielding are managed by the Army's Tactical Radios Project Office.

4137 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

MUOS Program

Technology, Design, and Production Maturity

The MUOS program's technologies are mature, its design is stable, and its manufacturing process maturity has increased. The first two satellites have been launched and three other satellites are being built. We could not assess whether critical manufacturing processes were in control as the program does not collect statistical process control data. The program has experienced quality problems in the past that resulted in cost increases and schedule delays; however, the number of manufacturing defects on the space segment has decreased over time. According to the program, multiple corrective action boards collect and track all defects in manufacturing processes and the program uses this data to assess the maturity of production. Examples of specific metrics used include number of defects per 1,000 hours of touch labor, amount of deferred work and associated risk, and rate of resolving nonconformance issues. According to the program office, these metrics indicate continuing increases in MUOS production maturity and show program goals are being met.

Other Program Issues

The first MUOS satellite was launched in February 2012, 26 months later than initially planned, and the second satellite was launched in July 2013. According to the program office, the remaining MUOS satellites are needed because most on-orbit UFO satellites are past their design lives. Two of these unexpectedly failed—one in June 2005 and another in September 2006—and a third was taken off-line in November 2012. Program officials stated that the required availability level of legacy UHF communication capabilities has been provided and based on the projected launch schedule for the remaining MUOS satellites, the required availability of legacy UHF communication capabilities is predicted to be maintained through May 2020.

Since 2007, we have reported that synchronizing deliveries of MUOS satellites with compatible Joint Tactical Radio System (JTRS) Handheld, Manpack, and Small Form Fit (HMS) terminals has been a challenge. Launching MUOS satellites is important to sustain legacy UHF communications capability. However, utilization of over 90 percent of MUOS's planned capability is dependent on the development of the MUOS waveform—which completed formal qualification testing in November 2012—and porting the MUOS capability onto operational user terminals. The Army's HMS program is developing the first operational terminal to incorporate the MUOS waveform. Additionally, according to the MUOS program, other vendors wanting to integrate the MUOS waveform into their radios are being supported with MUOS waveform software and government-operated MUOS test resources.

To date, the HMS program has conducted multiple developmental tests on the Manpack radio and an operational test was conducted in 2012. This testing, conducted without the MUOS waveform, found that the terminals did not meet all performance and reliability requirements. However, according to the MUOS program, the radio demonstrated improved performance at subsequent test events and was selected for fielding to Army units without the MUOS waveform due to the capability increases it would provide. Limited testing has been conducted on terminals with the MUOS waveform to date. Operational testing and initial fielding of the HMS terminals with the MUOS waveform is planned to begin in 2014.

Program Office Comments

In commenting on a draft of this assessment, the program officials provided technical comments, which were incorporated as appropriate.

MQ-1C Gray Eagle Unmanned Aircraft System (MQ-1C Gray Eagle)

The Army's MQ-1C Gray Eagle unmanned aircraft system (UAS) will perform reconnaissance, surveillance, target acquisition, and attack missions either alone or with other platforms such as the Longbow Apache helicopter. Each platoon-sized system includes four aircraft, payloads, data terminals, automatic take off and landing systems, ground control stations, and support equipment. The Army procured less-capable quick reaction capability variants to address urgent needs, but these systems are not included as part of the Gray Eagle program.

Source: General Atomics Aeronautical Systems, Inc.

Program Essentials

Prime contractor: General Atomics Aeronautical Systems, Inc.
Program office: Redstone Arsenal, AL
Funding needed to complete:
R&D: $76.8 million
Procurement: $849.5 million
Total funding: $1,115.4 million
Procurement quantity: 6

Program Performance (fiscal year 2014 dollars in millions)

	As of 04/2005	Latest 08/2013	Percent change
Research and development cost	$362.7	$1,006.5	177.5
Procurement cost	$705.1	$3,227.8	357.8
Total program cost	$1,067.8	$4,859.2	355.1
Program unit cost	$213.552	$156.750	-26.6
Total quantities	5	31	520.0
Acquisition cycle time (months)	50	95	90.0

Total quantities include 31 platoon systems consisting of four aircraft and related equipment. The program will also buy 21 aircraft to replace attrition losses and 7 training aircraft, for a total of 152.

The Gray Eagle program received approval to begin full-rate production in June 2013 with its technologies, design, and manufacturing processes mature. However, design changes and supplier base issues put the program's cost and schedule at risk. Program officials said they are considering a change to the aircraft tail, which would be costly and require retrofitting the entire fleet. The program is also developing a new ground control station which will not undergo operational testing until May 2015. In addition, a production readiness review conducted in support of the program's full-rate production decision identified several high risk supplier base issues that pose uncertainty for the program's cost and schedule. The program is tracking these risks and program officials said its suppliers have mitigation strategies in place.

4139 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

MQ-1C Gray Eagle Program

Technology and Design Maturity

The Gray Eagle program reported that all five of its critical technologies are mature and have been demonstrated in a combat environment. Program officials stated that the design is generally stable; however, there is the potential for design changes if the program decides to integrate a new aircraft tail that the program's contractor is developing in response to an aircraft accident in 2009. Program officials said that integrating the new tail design would be costly as it would require retrofitting the entire Gray Eagle fleet, although it would provide increased reliability and endurance. A decision is expected in fiscal year 2014 on whether to move forward with the retrofit based on affordability considerations.

Production Maturity

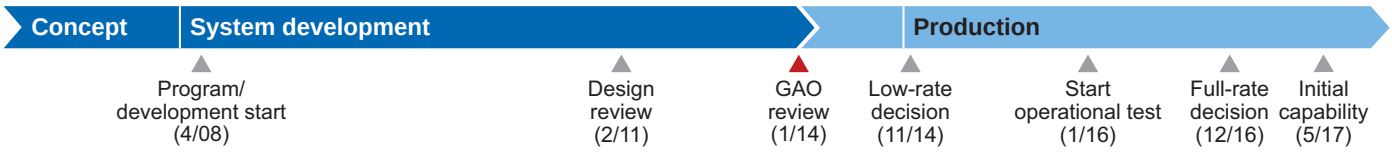
The Gray Eagle's 2013 production readiness assessment reported that its manufacturing processes are mature and at the level recommended by DOD guidance for the start of full-rate production. The program was approved to begin full-rate production of 49 aircraft and support equipment in June 2013 and awarded the first of three planned full-rate production contracts in September 2013. However, the program is tracking several risks related to its supplier base. For example, the Gray Eagle prime contractor is currently flight testing a new aircraft engine to replace the legacy engine because the legacy engine supplier went into bankruptcy. Program officials noted they have enough engines on hand for the first full-rate production lot, identifying a new engine source poses technical, cost, and schedule risks to the program, according to the production readiness review. The program and the Defense Contract Management Agency are also tracking other risk items related to multiple suppliers' financial concerns as well as quality control, but program officials said its suppliers have mitigation strategies to address these risks.

Other Program Issues

The Gray Eagle system completed initial operational test and evaluation in August 2012. DOD's Director, Operational Test and Evaluation (DOT&E), found the system to be operationally effective with the potential to provide effective support to combat units and suitable at meeting its performance and combat availability requirements. However, several recommended improvements were identified related to tactics, techniques, and procedures; training; and the design of the ground control station shelter. Specifically, DOT&E found that the Army needs to improve integration of Gray Eagle into employment concepts and improve soldier training. In addition, the design of the current ground control station degrades aircraft operator efficiency. According to the program office, the Army has already begun to address these issues and plans to re-evaluate them at the planned follow-on test and evaluation in May 2015. The follow-on test will also be used to assess new hardware and software the program is developing to replace the current ground control station as well as assess its net readiness capabilities. Once testing is complete, program officials said the Army will deploy the new ground control station to fielded units and will train Gray Eagle operators on the new system.

Program Office Comments

In commenting on a draft of this assessment, the program office provided technical comments, which were incorporated as appropriate.



4140 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

MQ-4C Triton Unmanned Aircraft System (MQ-4C Triton)

The Navy's MQ-4C Triton is intended to provide a persistent maritime intelligence, surveillance, and reconnaissance (ISR) capability even when no other naval forces are present. Triton will operate from five land-based sites worldwide as a part of a family of maritime patrol and reconnaissance systems that recapitalizes the Navy's airborne ISR assets. Planned improvements include a signals intelligence capability and an upgrade to the systems communication relay. The Triton is based on the Air Force's RQ-4B Global Hawk air vehicle.

Program Essentials

Prime contractor: Northrop Grumman Systems Corporation
Program office: Patuxent River, MD
Funding needed to complete:
- R&D: $770.8 million
- Procurement: $9,542.6 million
- Total funding: $10,519.3 million
- Procurement quantity: 65

Program Performance (fiscal year 2014 dollars in millions)

	As of 02/2009	Latest 12/2012	Percent change
Research and development cost	$3,304.2	$3,639.0	10.1
Procurement cost	$9,805.7	$9,592.7	-2.2
Total program cost	$13,512.2	$13,544.2	0.2
Program unit cost	$193.032	$193.488	0.2
Total quantities	70	70	0.0
Acquisition cycle time (months)	92	109	18.4

The Triton's critical technology is mature, the design is stable—although not yet demonstrated—and the program reports that manufacturing processes will be ready to support low-rate production. Testing on the first development aircraft began in September 2012 and first flight occurred in May 2013. However, the program discovered design challenges during integration and testing and had its production budget reprioritized in fiscal year 2014. Alternatives for an air-to-air radar subsystem are being considered and the program's production decision has been delayed by about one year. The program office authorized the prime contractor to develop a new target baseline and schedule that takes into account the program's increased costs and schedule delays.

4141 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

MQ-4C Triton Program

Technology and Design Maturity

The Triton program's one critical technology—a hydrocarbon sensor—was found to be mature by an April 2011 technology readiness assessment. However, the air-to-air radar subsystem (AARSS), which will enable Triton to sense and avoid other aircraft, has faced developmental delays and cost overruns. As a result, the Navy ordered work to be stopped on the subsystem in April 2013 and is currently examining alternatives.

The Triton design is stable and according to the program office, all design drawings are releaseable to manufacturing, but a fully outfitted system-level prototype has not yet been tested. Testing of the first development aircraft began in September 2012, followed by first flight in May 2013. Program officials expect the second development aircraft, which was expected to be the first with a full sensor suite and a sense-and-avoid capability, to begin testing in 2014. However, as a result of developmental delays, they do not plan for AARSS to be incorporated on the aircraft until 2016 for operational evaluation. Software development and maturity also remain areas of potential risk. The program plans to utilize nearly 8 million lines of code, more than 20 percent of which will be new. Though some software integration challenges discovered during testing were resolved in 2013, two more phases of software development and installation are scheduled for completion before the aircraft enters into operational evaluation.

Production Maturity

In November 2011, the program received approval to build three air vehicles and ground stations, in part to demonstrate its manufacturing processes prior to production. Program officials noted that one of these three aircraft will no longer be produced because of new priorities within the Navy's budget. The program reports that manufacturing processes will be able to support low rate initial production after the production decision is made. The Triton aircraft is based on the Air Force's RQ-4B Global Hawk and uses sensor components and subsystems from other platforms. There are some structural changes to the airframe, but none of these require significant changes to manufacturing processes. The program plans to award a contract for long lead material one year prior to the low-rate initial production contract award.

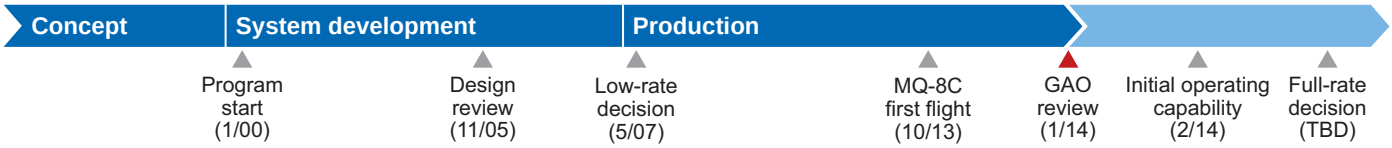
Other Program Issues

The Triton program's production decision has been delayed by about one year because of design adjustments to ensure airworthiness and software stability issues discovered during system integration and testing as well as the Navy's decision to reprioritize the program's production funding for fiscal year 2014. The program office authorized the prime contractor to develop a new target baseline and schedule to take into account increased costs and delays. Program officials expected to receive the revised baseline and schedule in December 2013. According to program officials, the delay has allowed the contractor to resolve some technical issues.

In September 2013, the Global Hawk program experienced an anomaly with a navigation system held in common with Triton. Though the Triton program did not experience the same anomaly, test flights were suspended until a work around was identified. The Air Force is continuing its investigation into the cause of the navigation system issue.

Program Office Comments

In addition to providing technical comments, the program office noted that the Triton UAS program continues to demonstrate success during its system development and demonstration phase as evidenced by the nine initial envelope expansion flights conducted to date. As reported in the December 2012 Selected Acquisition Report, the program breached the acquisition program baseline cost threshold for research, development, test and evaluation and the schedule thresholds for reaching production start, operational evaluation start, full rate production, and initial operational capability. The program has been re-planned to adjust the cost and schedule remaining for the system development and demonstration contract. A proposed program baseline revision is in work and all parameters will be reviewed, to include the operating and support cost estimate. The program continues to benefit from strong support within the Department of the Navy.



4142 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

MQ-8 (Fire Scout)

The Navy's MQ-8 unmanned aerial vehicle is intended to provide real-time imagery and data in support of intelligence, surveillance, and reconnaissance missions. An MQ-8 system is comprised of up to three air vehicles with sensors, two ground control stations, and one recovery system. The air vehicle launches and lands vertically, and operates from ships and land. The MQ-8 is intended for use in various operations, including surface, anti-submarine, and mine warfare. We assessed the latest variant, the MQ-8C.

Program Essentials

Prime contractor: Northrop Grumman
Program office: Patuxent River, MD
Funding needed to complete:
- R&D: $0.0 million
- Procurement: $1,685.1 million
- Total funding: $1,685.1 million
- Procurement quantity: 145

Program Performance (fiscal year 2014 dollars in millions)

	As of 12/2006	Latest 09/2013	Percent change
Research and development cost	$629.0	$711.8	13.2
Procurement cost	$1,769.6	$2,099.4	18.6
Total program cost	$2,750.7	$2,811.2	2.2
Program unit cost	$15.540	$16.064	3.4
Total quantities	177	175	-1.1
Acquisition cycle time (months)	104	169	62.5

The Navy ceased production of the MQ-8B variant and in April 2012 awarded a contract to begin development and production of the new MQ-8C with a larger airframe to improve range, endurance, payload, and future carrying capacity. MQ-8C relies on common, mature technologies with the MQ-8B. The engineering design of the MQ-8C is complete as it is based on the MQ-8B design, which appeared to be stable before halting production. The program completed operational test and evaluation of MQ-8B in December 2013 and a Quick Reaction Assessment of MQ-8C will be completed in the fourth quarter of fiscal year 2014. The program plans to conduct an acquisition strategy review in the first quarter of fiscal year 2014 that assesses overall program health, including production readiness. In 2015, the program plans to test the MQ-8C on the Littoral Combat Ship, the platform originally intended for MQ-8B.

4143 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Fire Scout Program

Technology and Design Maturity

According to the program office, MQ-8C is 90 percent common with the previously developed MQ-8B, with the primary difference being structural modifications to accommodate the MQ-8C's larger airframe and fuel system. The MQ-8C relies on mature technologies common to the MQ-8B and does not introduce any new technologies. Program officials stated that the engineering design of MQ-8C is complete, as it is based on the MQ-8B design, which appeared to be stable prior to the Navy's decision to cease production of the system in 2012. Program officials noted that a revision to the air vehicle to accommodate increased payload remains to be completed, but they expect the issue to be resolved by early calendar year 2014. The first flight of the MQ-8C occurred in October 2013.

Production Maturity

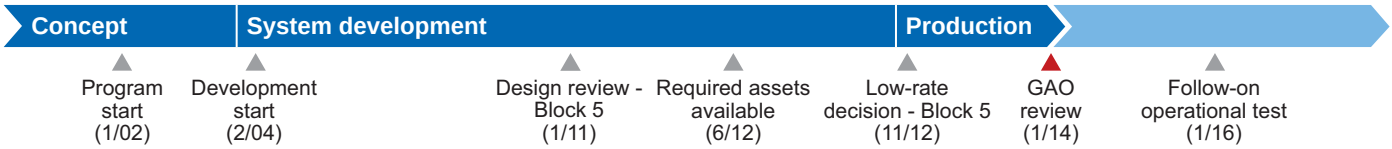
The program plans to produce the MQ-8C on the same production line as the MQ-8B and officials stated that they have not experienced challenges in transitioning production between the systems. The program's production processes for MQ-8B have been demonstrated, but we could not assess whether critical manufacturing processes were in control as the program does not collect data on statistical process controls or assess process capabilities using manufacturing readiness levels. The program suspended production of MQ-8B and awarded a development and production contract for 8 MQ-8Cs in April 2012. The program earlier intended to resume production of the MQ-8B aircraft in 2015 to align with the delivery of the Littoral Combat Ship—the platform from which MQ-8B is intended to operate—but the Navy plans to continue MQ-8C production instead. The Navy plans to award a third production contract for MQ-8C in March 2014 in support of the Joint Emergent Operational Need. Program officials stated that the date of the full-rate production decision has not been determined. Future procurements will be addressed in the updated acquisition strategy.

Other Program Issues

The program has shifted its focus to MQ-8C—an upgraded variant of the aircraft with improved range, endurance, payload, and future carrying capacity—due to a joint urgent operational need from U.S. Africa Command. According to program officials, the program is not requesting new funds for MQ-8C, but plans to use funding slated for MQ-8B. MQ-8C is not required to conform to many of the acquisition practices followed by other programs as it is being developed to fill a joint urgent operational need. However, a Quick Reaction Assessment is planned for MQ-8C 3 to 4 months prior to ship deployment, which is expected to be in the first quarter of fiscal year 2015. The program is planning to test the MQ-8C at-sea in 2014 on the DDG-109 and on the Littoral Combat Ship in 2015. The program completed operational test and evaluation of MQ-8B in December 2013 and a Quick Reaction Assessment of MQ-8C will be completed in the fourth quarter of fiscal year 2014. The program plans to conduct an acquisition strategy review in the first quarter of fiscal year 2014 that assesses overall program health, including production readiness.

Program Office Comments

According to the program office, the MQ-8 Fire Scout system has accumulated over 4,500 flights totaling more than 12,000 flight hours with the MQ-8B air vehicle. In the first quarter of fiscal year 2014, the system was assessed by the Navy Operational Test community aboard USS Roberts and completed an Initial Operational Capability Supportability Review in preparation for fleet transition and Initial Operational Capability in second quarter fiscal year 2014. The Fire Scout system with the MQ-8C Endurance Upgrade aircraft is being procured in response to a Joint Emergent Operational Need from Africa Command. The Navy is planning to incorporate the MQ-8C variant into the Fire Scout system as part of its updated acquisition strategy. First flight of the MQ-8C occurred on October 31, 2013. As of January 2014, the MQ-8C has performed more than 32 test flights and accumulated over 46 flight hours. In commenting on a draft of this assessment, the program office provided technical comments, which were incorporated where deemed appropriate.



4144 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

MQ-9 Reaper Unmanned Aircraft System (MQ-9 Reaper)

The Air Force's MQ-9 Reaper is a multirole, medium-to-high-altitude endurance unmanned aircraft system capable of flying at higher speeds and altitudes than its predecessor, the MQ-1 Predator A. The Reaper is designed to provide a ground-attack capability to find, fix, track, target, engage, and assess small ground mobile or fixed targets. Each system consists of four aircraft, a ground control station, and a satellite communications suite. We assessed the increment I Block 5 configuration and made observations on Block 1.

Source: U.S. Air Force.

Program Essentials

Prime contractor: General Atomics Aeronautical Systems, Inc.
Program office: Wright-Patterson AFB, OH
Funding needed to complete:
R&D: $843.3 million
Procurement: $6,055.7 million
Total funding: $6,921.1 million
Procurement quantity: 161

Program Performance (fiscal year 2014 dollars in millions)

	As of 02/2008	Latest 09/2013	Percent change
Research and development cost	$441.9	$1,613.0	265.0
Procurement cost	$2,220.7	$10,826.4	387.5
Total program cost	$2,773.5	$12,517.3	351.3
Program unit cost	$26.414	$30.983	17.3
Total quantities	105	404	284.8
Acquisition cycle time (months)	79	100	26.6

The Reaper's critical technologies are mature and all design drawings have been released. Delays in manufacturing, delivery of technical data, and developmental testing have pushed back critical software releases for both Block 1 and Block 5 configurations. The MQ-9 Reaper was approved for low-rate initial production in November 2012, but has not yet demonstrated that critical manufacturing processes are in control. The program originally expected to complete operational testing no later than October 2014; however manufacturing and other delays have caused the program to postpone the completion of testing until January 2016. The program's full-rate production decision was changed to an in-process review because more than half of the aircraft will be procured prior to a full-rate production decision.

4145 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

MQ-9 Reaper Program

Technology and Design Maturity

The Reaper's critical technologies are considered mature and its design is stable. Manufacturing issues, as well as delays in the delivery of technical data and developmental testing have pushed back critical Block 1 and Block 5 configuration software releases by 8 months and 15 months, respectively. Program officials now plan to field the Block 5 software in March 2016. The Block 5 configurations include capability enhancements from the Block 1 configuration such as updates to the radar, data link, sensor, landing gear, software, and ground control stations. Until testing is completed, the Block 5 system remains at risk of design changes.

Production Maturity

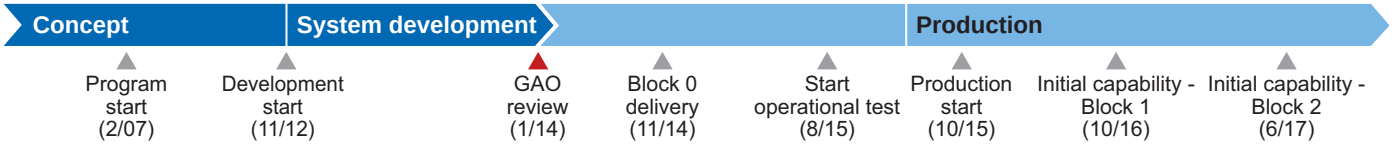
The Air Force approved low-rate initial production of the MQ-9 Reaper Block 5 Increment in November 2012. According to program officials, the Block 5 manufacturing processes have reached the level of maturity recommended by DOD guidance for the start of low-rate production. However, the program's manufacturing readiness level did not indicate that its production processes were in statistical control, as recommended by our best practices. MQ-9 Reaper production deliveries have slowed over the past year because of delinquencies in completing technical data, software delays, and fuel tank issues that required engineering design changes to the production line and retrofitting aircraft that had already been produced. As of December 2013, 21 Block 1 aircraft have been produced, but are still awaiting the necessary software capability upgrades before they can be delivered. Until these software upgrades are complete, aircraft are only being delivered based on urgent needs. According to program officials, the program has developed an aircraft delivery recovery plan that should allow deliveries to be back on track by April 2014.

Other Program Issues

The program office declared a breach to the MQ-9 Block 5 program's schedule baseline in May 2013 because of delays associated with manufacturing, technical data, and developmental testing. The program originally expected to complete operational testing no later than October 2014. Operational testing will now be complete in January 2016. This schedule change was approved by the configuration steering board in December 2013. At this time, the full-rate production decision was changed to an in-process review since more than half of the aircraft will be procured prior to the full rate production decision. The program office is in the process of updating the acquisition program baseline.

Program Office Comments

In commenting on a draft of this assesment, program officials noted that since the program office declared a breach in May 2013, the program office and contractor resolved issues that delayed schedule and are implementing processes to improve quality for future success. The re-baselined MQ-9 Block 5 schedule was approved at the Air Force review board in August 2013 and the configuration steering board in December 2013. The program office is updating the acquisition program baseline to reflect program changes. Follow-on test and evaluation is now planned to complete in January 2016. The program office is currently in formal developmental test of Block 5. The program office also took delivery of the first Block 5 aircraft in November 2013 to assist with developmental test and technical order development. The program office also provided technical comments that were incorporated as appropriate.



4146 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Next Generation Operational Control System (GPS OCX)

The Air Force's Global Positioning System Next Generation Operational Control System (GPS OCX) is to replace the current ground control system for legacy and new GPS III satellites. GPS OCX is expected to ensure reliable and secure delivery of position and timing information to military and civilian users. The Air Force plans to develop GPS OCX in blocks, with each block delivering upgrades as they become available. We assessed the initial three blocks, which support the launch, checkout, and operation of GPS II and III satellites.

Prime contractor: Raytheon
Program office: El Segundo, CA
Funding FY14 to FY19:
R&D: $1,662.8 million
Procurement: $0.0 million
Total funding: $1,662.8 million
Procurement quantity: 0

Program Performance (fiscal year 2014 dollars in millions)

	As of	Latest 12/2012	Percent change
Research and development cost	NA	$3,470.3	NA
Procurement cost	NA	$0.0	NA
Total program cost	NA	$3,470.3	NA
Program unit cost	NA	$3,470.350	NA
Total quantities	NA	1	NA
Acquisition cycle time (months)	NA	55	NA

Table includes costs through fiscal year 2019.

GPS OCX entered system development in November 2012. The program consists of three blocks: Block 0, intended to support the launch and checkout of GPS III satellites; Block 1, designed for command and control of the GPS II and III satellites; and Block 2, which is expected to support, monitor, and control additional navigation signals. The program's 14 critical technologies are nearing maturity, but seven of those technologies are not expected to reach full maturity until the end of fiscal year 2015 or later, nearly 3 years after the program began system development. Aligning the schedules for GPS OCX and GPS III is a risk for both programs. Block 1 is scheduled to become operational by October 2016, 6 months after the date of GPS III's availability for launch.

4147 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

GPS OCX Program

Technology Maturity

GPS OCX entered system development in November 2012 with all of its 14 critical technologies tested in a relevant environment, but not a realistic environment. According to program officials, these technologies will not reach full maturity until the program integrates together all of the key subsystems and components and tests them in the factory. The first of these tests is scheduled to occur near the end of fiscal year 2014 and is expected to result in seven of the technologies reaching full maturity. The remaining seven technologies are not expected to reach full maturity until the end of fiscal year 2015 or later, nearly three years after the program began system development.

Design and Production Maturity

GPS OCX is primarily a software development program and is expected to provide capabilities in three block deliverables. Block 0 is intended to provide initial capability for launch control and checkout of GPS III satellites. Block 1 is designed to operate legacy and new GPS satellites, including new civilian signals, and Block 2 is expected to add operational control of new international and modernized military signals.

According to the program office, software is being developed and tested incrementally with a critical design review after each stage to ensure the design is stable. Software development for Block 0 is nearly complete and all remaining testing is scheduled for completion at the beginning of fiscal year 2015. The program has started development activities for Block 1, which program officials expect to be completed in October 2016.

Program officials expect to integrate the software and hardware components for all of Blocks 0 and 1 and test them as a prototype to ensure the system will work as intended. According to GAO's best practices, this integrated prototype test should occur before critical design review. However, program officials stated that the test will not happen until December 2015, 18 months after the final critical design review and ten months before Block 1 is scheduled to be complete. Program officials reported that they had used other knowledge-based practices to increase confidence in the stability of the design such as identifying key product characteristics and establishing a reliability growth curve.

Other Program Issues

The program experienced significant schedule delays while in technology development. This, combined with the program's late start relative to GPS III, has resulted in considerable risk in aligning the schedules of GPS OCX and GPS III satellites. Block 1, which is to provide command and control for GPS III satellites on orbit, is not scheduled to become operational until October 2016, 6 months after the first GPS planned GPS III satellite is expected to be available for launch. Until Block 1 is operational, the GPS III satellite will have very limited capabilities and Air Force officials said they do not plan to launch a second GPS III satellite until that time.

Program Office Comments

In commenting on a draft of this assessment, the program office provided technical comments, which were incorporated as appropriate.

4148 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

P-8A Poseidon Multi-Mission Maritime Aircraft (P-8A)

The Navy's P-8A Poseidon is a commercial derivative aircraft that will replace the P-3C Orion. Its primary roles are antisubmarine warfare, antisurface warfare, and intelligence, surveillance, and reconnaissance. The P-8A is part of a family of systems, including the MQ-4C Triton unmanned aircraft system, which will perform maritime patrol missions and support the Navy's maritime warfighting capability. The program plans to field capabilities in three increments. We assessed increment one and made observations on increments two and three.

Program Essentials

Prime contractor: The Boeing Company
Program office: Patuxent River, MD
Funding needed to complete:
R&D: $552.4 million
Procurement: $15,984.3 million
Total funding: $16,811.2 million
Procurement quantity: 80

Program Performance (fiscal year 2014 dollars in millions)

	As of 06/2004	Latest 08/2013	Percent change
Research and development cost	$7,921.2	$8,826.6	11.4
Procurement cost	$24,574.2	$25,122.3	2.2
Total program cost	$32,640.1	$34.336.0	5.2
Program unit cost	$283.827	$281.442	-0.8
Total quantities	115	122	6.1
Acquisition cycle time (months)	160	164	2.5

The P-8A entered production in August 2010 with mature technology, a stable design, and proven production processes. The P-8A completed initial operational testing in March 2013 and was found to be operationally suitable and effective. The test report identified five significant deficiencies and recommended that the P-8A be introduced to the fleet with several operational restrictions. According to the program office, it has plans in place to correct or otherwise resolve these deficiencies. The program's full rate production decision was delayed from July 2013 until January 2014 in part to enable additional assessment of deficiency corrections from developmental test and evaluation. To maintain production continuity, and utilize available funding, the program awarded a fourth low-rate production contract. The first P-8A operational deployment began in December 2013.

4149 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

P-8A Program

Technology Maturity

The P-8A entered production in August 2010 with a fully mature and sole critical technology, the hydro-carbon sensor. The sonobuoy launcher, which at one time was also considered a critical technology, has experienced issues in testing and fixes are still being made to improve its performance and reduce operator errors.

Design Maturity

Overall, the design of the P-8A is stable, but the number of design drawings continues to grow due to deficiencies discovered in testing. The number of releasable drawings increased by 16 percent since our last assessment and 95 percent of the total drawings have been released.

Production Maturity

The manufacturing processes for P-8A are mature and the program has improved the acceptance process after minor anomalies and maintenance issues were discovered with each of the first five production aircraft. According to program officials, Boeing has implemented additional pre-acceptance flights, which have reduced the number of issues discovered by the government during the formal acceptance process. More recently, the Defense Contract Management Agency reported the late delivery of spare parts could affect aircraft deliveries by reducing the program's ability to swap out defective parts when needed. The program office stated that it has addressed this issue and aircraft deliveries had not been impacted to date.

Other Program Issues

The P-8A program completed initial operational test and evaluation in March 2013. The final test report found the aircraft to be operationally effective and suitable. The report identified five significant deficiencies that are typically corrected before operational deployment and the operational test staff recommended that the P-8A enter the fleet with several operational restrictions. According to the program office, it has plans in place to correct or otherwise resolve these deficiencies. For example, to maintain main fuel tank temperatures within required operating limits during hot weather ground operations, the program is re-qualifying key components to higher operating limits and developing new planning tools and fueling procedures. The first operational deployment of P-8A commenced in December 2013. Follow-on operational testing, which includes verifying test fixes discovered previously in developmental testing, began in October 2013.

The Navy delayed the program's full rate production decision from July 2013 until January 2014 in order to allow enough time for the program to assess deficiency corrections. To maintain production line continuity, and utilize available program funding, the program awarded a fourth low-rate initial production contract for 13 aircraft.

During increments 2 and 3, the program plans to integrate additional capabilities into the P-8A. Increment 2, which is being managed as a series of engineering changes rather than a separate development effort, includes various improvements to the system's antisubmarine warfare and other capabilities. The program eventually plans to retrofit previously manufactured aircraft with the planned Increment 2 capabilities. The Navy plans to conduct a separate system development phase for increment 3. The improvements include changes to the P-8A's system architecture to allow for rapid integration of new applications and services. The program plans to conduct full and open competition for its increment 3 contracts and to purchase the data rights for the new, more open architecture.

Program Office Comments

In commenting on a draft of this assessment, the program office stated that following an extensive operational test period, the Navy's operational test authority reported that the P-8A aircraft is operationally effective and suitable and recommended it for fleet introduction. The program office added that this conclusion is consistent with the fleet's experience with the aircraft during extensive aircraft transition and pre-deployment training cycles. The first such cycle began with the delivery of the first P-8A aircraft to an operational squadron in May 2012, included the attainment of initial operational capability in November 2013, and culminated with the departure of the first fully trained squadron for operational deployment later that same month. In December 2013, the thirteenth of 37 low-rate initial production aircraft was delivered to fleet squadrons, with all deliveries on or ahead of schedule. The program office also provided technical comments, which were incorporated as appropriate.

4150 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Paladin Integrated Management (PIM)

The Army's Paladin Integrated Management (PIM) system consists of two individual platforms, a self-propelled howitzer (SPH) and a tracked ammunition carrier that provides operational support. The SPH is a tracked, aluminum armored vehicle with a 155 millimeter cannon. The PIM will provide improved sustainability over the current Paladin M109A6 howitzer fleet through the incorporation of a newly designed hull; modified M2 Bradley infantry fighting vehicle power train, suspension system, and track; and a modernized electrical system.

Funding needed to complete:
- R&D: $367.7 million
- Procurement: $5,684.8 million
- Total funding: $6,052.5 million
- Procurement quantity: 556

Program Performance (fiscal year 2014 dollars in millions)

	As of 02/2012	Latest 10/2013	Percent change
Research and development cost	$1,060.1	$1,101.7	3.9
Procurement cost	$5,973.4	$5,886.3	-1.5
Total program cost	$7,033.5	$6,987.9	-0.6
Program unit cost	$12.085	$12.523	3.6
Total quantities	582	558	-4.1
Acquisition cycle time (months)	118	118	0.0

The program was approved for low-rate initial production in October 2013 with the first production delivery scheduled for March 2015. Program officials stated that a lack of available staff, staff furloughs, loss of workforce overtime, and a reduction in travel funding due to sequestration caused the production decision date to slip from June 2013 to October 2013. The program was approved for production with its two critical technologies fully mature and a stable design. The program, as originally structured, was not a major defense acquisition program, but was elevated to major defense acquisition program status due to rising cost estimates. The program has also experienced schedule slippage due to delays in the start of developmental testing and changes to force protection and survivability requirements that drove the addition of new armor kits and a new ballistic hull and turret.

4151 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

PIM Program

Technology Maturity

The program office identified two technologies critical to the PIM program; power pack integration and the ceramic bearing of the generator assembly. Both technologies have been assessed as fully mature. The program office identified these technologies as critical based on concerns about their performance at high temperatures. While neither technology is new or novel, failure of either would represent major program risk. In addition, increases in vehicle weight due to the addition of material to improve survivability, minimal power pack space, and other integration issues may degrade the ability to meet automotive performance requirements.

Design Maturity

According to the program office, the design is currently stable with all of the expected drawings released; however, the program faces a number of design challenges as it moves forward. The current contractor for the engine and transmission may cease production due to lack of orders. If this occurs, production with another vendor may be necessary and could result in a redesign of the engine and engine compartment. Production with another vendor has the potential for cost growth between $32 to $100 million and a significant schedule delay. Additionally, after the critical design review, the program manager identified a number of corrective actions, producibility, and obsolescence engineering changes to the PIM design that are scheduled to be implemented between low-rate initial production and initial operational test and evaluation. If significant issues are uncovered during the testing of these engineering changes, then there is potential for cost growth and delays in production.

Production Maturity

The program was approved for low-rate initial production in October 2013 with the first production vehicle scheduled for delivery in March 2015. As of August 2013, the program office indicated that a number of manufacturing processes and systems are below the maturity levels required by best practices. The program reported that the capability to produce the vehicles in a pilot-line environment will be not be demonstrated until after production begins. Our best practices work has shown that programs risk missing cost and schedule targets if their manufacturing processes are not demonstrated and in control before production begins. Program officials have indicated that there is a minimal risk that the PIM final assembly facility may not be ready in time to support initial PIM shipments.

Other Program Issues

The program's current plans are schedule driven, with limited time for correction of deficiencies identified in developmental testing and little flexibility with individual component test schedules. The program is waiting for low-rate initial production vehicles before verifying most corrective actions. Additionally, program officials stated that the PIM and the Bradley infantry fighting vehicle programs currently share a common path for the suspension and power train, but if the Bradley program diverges from this path there could be cost and schedule impacts for the PIM program.

Program Office Comments

In commenting on a draft of this assessment, the Army stated that the PIM program is on track for its full-rate decision scheduled for January 2017. Additionally, technical comments were provided, which were incorporated as appropriate.

Presidential Helicopter Fleet Replacement Program (VXX)

The Navy's VXX program is to provide a replacement helicopter fleet that will be used to transport the President, Vice President, heads of state, and others. As a successor to the terminated VH-71 program, the VXX fleet of 21 new helicopters will replace the current fleet of 19 VH-3D and VH-60N legacy helicopters and two training aircraft (to be delivered in 2014). The program plans to enter system development in March 2014. Until the VXX helicopters are available, the Navy is extending the availability of the legacy aircraft.

Total quantities	NA	23	NA
Acquisition cycle time (months)	NA	77	NA

Table includes costs through fiscal year 2018.

The Navy made progress in establishing a limited development effort that reflects trade-offs made among cost, schedule, risk, and performance. Since April 2012, the program completed its analysis of alternatives, in which affordability and cost control are key factors, finalized the requirements and acquisition strategy, and was granted a waiver to the competitive prototyping requirement. Program affordability and timeliness are achieved by maintaining a candidate platform's current airworthiness certification, leveraging mature technologies, and through Government definition of the mission systems architecture and related avionics. To minimize risk, a sub-system preliminary technical readiness assessment was conducted in February 2013. However, a system level preliminary design review has been deferred until after the March 2014 start of system development.

Attainment of Product Knowledge

4153 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

VXX Program

Technology Maturity

The program reports the key technologies to be provided the government for integration into the VXX platform either already exist or are in development, some as legacy fleet aircraft upgrades. To minimize technical risk, the program completed a preliminary technical readiness assessment in February 2013; it was limited to the mission communication system (the only new technology envisioned for the VXX platform). As a result of this assessment, it was deemed the VXX mission communication system does not include any components that would be considered immature and classified as a critical technology element. Although the program has conducted a sub-system preliminary design review, it does not currently plan to conduct a preliminary design review until after the program enters system development. The statutory requirement for a preliminary design review has been waived, and will be conducted after the start of system development. To be consistent with the program's approved acquisition strategy, the language in the request for proposals encourages the use of mature off-the-shelf technologies that should only require standard engineering development practice to integrate and achieve installed systems performance.

Design Maturity

The VXX acquisition strategy is based on the integration of mature subsystems into an existing air vehicle. While minor changes to the platform, to accommodate integration of subsystems, are inevitable, change to major components such as drive train, rotors, engines and basic structure is highly discouraged. Any design elements that contain immature technology or that might be deemed a critical technology element are discouraged. The request for proposals encouraged offerors to remain within the existing airworthiness qualification of the baseline aircraft from which the VXX would be derived. The government does not intend to impose bottom-up airworthiness criteria that would drive redesign, but plans to leverage the current certification basis with the cognizant civil or U.S. military airworthiness certification authority to achieve a Naval Air Systems Command flight clearance.

Production Maturity

This program will leverage "green air vehicle" production by randomly selecting aircraft off the existing production line. This will save the government time and money by avoiding infrastructure costs associated with constructing a unique production facility and allow the program to meet its security production and supply requirements.

Other Program Issues

The program intends to award a single fixed-price type contract for the system development phase that will include options for low-rate initial production, full rate production, and associated logistics elements. The total aircraft quantity includes six aircraft to support system development, 17 production aircraft in three lots (six aircraft each in lot 1 and 2, and 5 in lot 3). The total period of performance will be approximately 8 years.

Program Office Comments

In commenting on a draft of this assessment, the program office provided technical comments, which were incorporated where deemed appropriate.

The Global Hawk program has mature technologies, a stable design, and mature manufacturing processes that are in statistical control. Congress directed the program to purchase the final three Block 30 aircraft and the program office awarded an advanced procurement contract in September 2013. All 45 Global Hawk aircraft have been purchased without a full-rate production decision. Congress directed the program to maintain the operational capability of Block 30 aircraft through December 2014. The Air Force will determine the final force structure following fiscal year 2015 and 2016 budget decisions. Block 40 aircraft operational testing has been delayed 6 months and delivery of a fully operational Block 40 capability has not been determined. The program fielded two Block 40 aircraft in September 2013, providing limited capability to the warfighter.

4155 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

RQ-4A/B UAS Global Hawk Program

Technology, Design, and Production Maturity

The critical technologies for the RQ-4B are mature, the basic airframe design is stable, and its manufacturing processes are mature and in statistical control. The RQ-4B aircraft consist of three configurations. Block 20 aircraft are equipped with an enhanced imagery intelligence payload, Block 30 aircraft have both imagery and signals intelligence payloads, and Block 40 aircraft have an advanced radar surveillance capability. The program is concurrently testing and fielding the multiple platform radar, the key capability for Block 40 aircraft. Due to software delays associated with another government system, Block 40 operational testing has slipped an additional 9 months, from January 2014 to October 2014, almost 4 years from the original estimate. Despite this, two Block 40 aircraft with the advanced radar capability were fielded in September 2013, providing a limited capability to the warfighter. Program officials stated that there is currently no formal date for the program to deliver a full capability Block 40 aircraft for operational use.

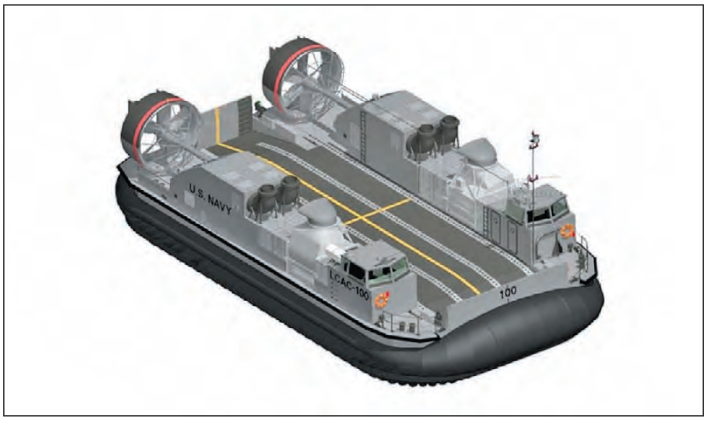
Other Program Issues

As part of its fiscal year 2013 budget request, DOD proposed terminating the Block 30 system in an effort to reduce program cost. However, in January 2013, Congress directed the Global Hawk program to purchase its remaining three planned Block 30 aircraft and mandated that the Air Force maintain the operational capability of Block 30 aircraft until December 31, 2014. The program reported that operating Block 30 aircraft beyond 2014 would create operational challenges and would require a substantial investment. According to officials, the Air Force will make a decision about the program force structure following future budget decisions. If the Air Force decides to retire Block 30 aircraft, almost half of all aircraft procured will be affected. In September 2013, the Air Force awarded an advanced procurement contract for the remaining three Block 30 aircraft and intends to award a firm fixed-price production contract in July 2014.

The Global Hawk program continues to operate without an established cost and schedule baseline, as its prior baseline was rescinded due to the program's Nunn-McCurdy breach in April 2011. The program had originally planned to re-establish its baseline in June 2011, but that review was superseded by the Air Force's proposed termination of Block 30. Program officials stated they are working with the Office of the Secretary of Defense and the Air Force to establish a new baseline.

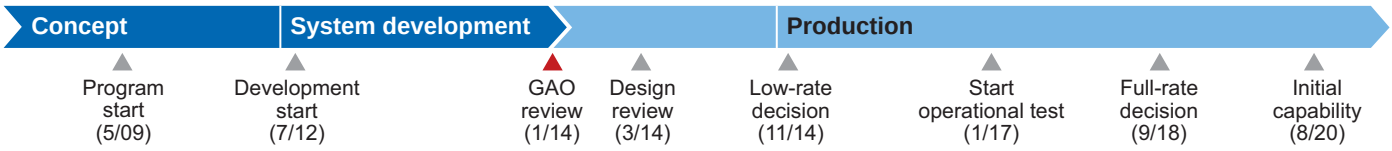
Production continues for Block 30 and Block 40 aircraft, despite the lack of an official full-rate production review. All 45 Global Hawk aircraft have been procured through low-rate initial production. The program does not plan to hold a production decision and, according to officials, continues to sustain operational aircraft.

The program had planned to begin development of a restructured ground control station and communications system to achieve a common architecture for both the Global Hawk and the Navy's Triton unmanned aircraft systems, has a similar design to Global Hawk. However, according to program officials the program could no longer afford the development effort due to fiscal constraints. Program officials noted that they have chosen to continue to maintain the current system and address obsolescence issues on an as-needed basis.



Program Office Comments

In commenting on a draft of this assessment, Air Force officials noted that the Air Force Operational Test and Evaluation Center completed the Block 40 operational utility evaluation in April 2013 in support of a Block 40 early operational capability. The two Block 40 aircraft that fielded in September 2013 were part of the early operational capability which provided the military with additional ground moving target support ahead of schedule. The Air Force also provided technical comments, which were incorporated as appropriate.



4156 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Ship to Shore Connector Amphibious Craft (SSC)

The Navy's SSC is an air-cushioned landing craft intended to transport personnel, weapon systems, equipment, and cargo from amphibious vessels to shore. SSC is the replacement for the Landing Craft, Air Cushion, which is approaching the end of its service life. The SSC is designed to deploy in Navy well deck amphibious ships, such as the LPD 17 class, and for use in assault and nonassault operations. The program entered system development in July 2012 and is scheduled for a critical design review in March 2014.

Program unit cost	$56.953	$55.524	-2.5
Total quantities	73	73	0.0
Acquisition cycle time (months)	135	135	0.0

The SSC program entered system development in July 2012 with its one critical technology—the fire suppressant system—mature. Two other technologies designated as technology watch items leverage existing mature technologies, but will need to be modified for use on SSC. The program has completed approximately 5 percent of expected design drawings seven months prior to critical design review scheduled for March 2014. Fabrication for the first two craft is scheduled to start three months after the critical design review. The acquisition strategy identified the plan to construct the first two craft concurrently as a risk due to the potential for design changes.

4157 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

SSC Program

Technology Maturity

The SSC program's one identified critical technology, the fire suppression system, entered system development as mature. According to program officials, the prime contractor is in the process of selecting a subcontractor to develop this system. According to the Navy, the system is expected to be lighter and more environmentally friendly than the system for the legacy craft.

DOD identified two other technologies—the gas turbine engine and the command, control, communications, computer and navigation (C4N) system—as critical technology watch-list items because of the possibility new technologies would need to be developed or modified for SSC. According to program officials, the gas turbine engine is mature, but needs modifications to convert it from aircraft to amphibious craft usage. In addition, program officials said that the prime contractor has selected a subcontractor to develop the C4N system and believes that the technology is low risk since it will leverage existing code from the legacy craft. Officials expect that the system will provide new operational features, including a pilot/co-pilot configuration that allows each operator to bring up the same display at separate consoles.

Design Maturity

As of August 2013, the contractor has released 42 of the 856 engineering drawings expected—almost 5 percent. Best practices suggest that completion of 90 percent of engineering drawing provides evidence of design stability. The program plans to demonstrate the stability of the SSC design at the program's production readiness review, currently planned for May 2014—2 months after the program's scheduled design review.

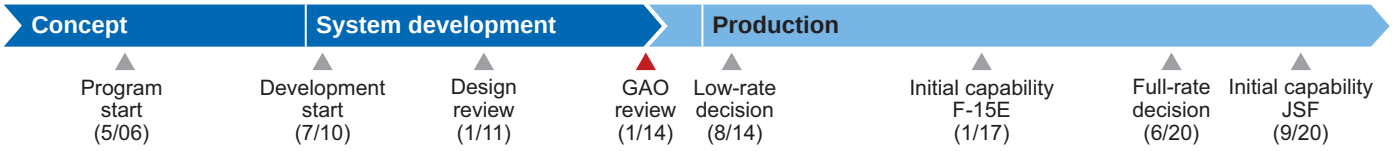
Fabrication of the first two craft are scheduled to begin in June 2014. The program office does not plan to assess critical manufacturing processes by the start of production. Program officials stated that they plan to have these processes partially demonstrated on a pilot production line before production start, noting that the program has pursued low risk technologies and a low risk design effort.

Production Maturity

The Navy plans to begin construction of the lead and follow-on craft concurrently—a strategy that has been identified as potentially risky due to the possibility that design changes identified in the first test and training craft would have to be incorporated in the second craft during construction. Despite this risk, the SSC program exercised an option to construct the second craft in December 2012—3 months earlier than planned. Program officials noted that the option was exercised earlier to take advantage of better pricing for certain long-lead construction materials. Overall, the program plans to exercise options for a total of six craft prior to delivery of the test and training craft in February 2017.

Program Office Comments

In commenting on a draft of this assessment, the program office noted that the Ship to Shore Connector is a technically mature, low risk program which is proceeding toward demonstration of design maturity. A detail design and construction contract was awarded in July 2012. The shipbuilder is conducting preliminary and critical design reviews of all major craft subsystems. The first craft's start of fabrication is planned for the third quarter of fiscal year 2014. The program office also provided technical comments which were incorporated where deemed appropriate.



4158 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Small Diameter Bomb Increment II (SDB II)

The Air Force's Small Diameter Bomb Increment II (SDB II) is designed to provide attack capability against mobile targets in adverse weather from standoff range. It combines radar, infrared, and semiactive laser sensors in a tri-mode seeker to acquire, track, and engage targets. It uses airborne and ground data links to update target locations as well as GPS and an inertial navigation system to ensure accuracy. SDB II will be integrated with F-15E, Joint Strike Fighter (JSF), F/A-18E/F, F-16C, and F-22A, as funding becomes available.

Acquisition cycle time (months)	72	79	9.7

The SDB II Program expects all of its critical technologies to reach full maturity by the time it enters low-rate production, which is planned to occur no earlier than August 2014—a 7-month delay from earlier estimates. The flight test program has experienced two failures, prompting a 6 month halt to flight testing in mid-2013. Since resuming flight test activities in October 2013, the program has conducted three successful flight tests. Although the design is stable, future design changes may be needed to address problems found in previous flight test failures. The flight test schedule is optimistic, requiring seven successful flight tests in 5 months. If additional flight test failures occur it could result in additional delays for the low-rate production decision.

4159 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

SDB II Program

Technology Maturity

SDB II's four critical technologies—guidance and control, multi-mode seeker, net ready data link, and payload—are scheduled to reach full maturity when the program has its low-rate production decision in August 2014, 4 years after the program entered system development. According to program officials, critical technologies have not directly contributed to any flight test failures.

Design Maturity

The number of design drawings is stable and the program has completed five successful guided flight tests. However, the flight test program experienced two failures that resulted in a 6-month halt in all guided test vehicle events until the program determined a root cause for the failures. The two failures were the result of the dome cover not deploying, preventing the seeker from acquiring the target, and a navigation error. Guided flight test activities resumed in October 2013 and, since then, the program has recorded three successful flight tests. Program officials stated that all of the failed tests have to be retested at a future date. Moreover, prior to the low-rate production decision, the program's test plan requires11 successful flight tests, including two live fire events.

Production Maturity

The program's low-rate production decision is expected no earlier than August 2014, a 7-month slip due to a delay in the program's system verification review, a prerequisite for this decision. The verification review will evaluate all of the program's flight tests and the system qualification testing. Eleven of the 12 subsystems have successfully passed qualification testing. However, all up round environmental qualification testing has been on hold since September 2013 due to subsystem issues.

According to program officials, the seeker subsystem is the final subsystem to complete qualification. The subsystem qualification was halted for issues related to a leak in the warhead case and seeker encoders that failed during vibration testing. A correction has been identified for the encoders and will be incorporated before testing resumes. The all up round qualification program has been placed on hold until the leak in the warhead case is resolved. The program has yet to identify a correction for the leak in the warhead. These delays have absorbed the entire 1-month qualification testing margin and contributed to the delayed system verification review, now scheduled for May 2014. According to program officials, the contractor will be adding additional vehicles to the all up round qualification program to lessen the effect that the pause has on the overall program schedule.

Other Program Issues

The program's test schedule prior to the low-rate production decision is optimistic. In addition to a 5-month delay in 2012, the test program recently ended a 6-month delay due to two flight test failures. According to program officials, the test program must have six successful flight tests prior to the May 2014 verification review. Additional flight test failures would likely further delay the low-rate production decision. Program officials also noted that future sequestration funding cuts may result in reduced production quantities or the inability to exercise contract options. This could force a renegotiation with the contractor for the first five production lots and the program could lose money that it saved through competition.

Program Office Comments

The Air Force concurred with this assessment. The Air Force also provided technical comments, which were incorporated as appropriate.

4160 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Space Fence

The Air Force's Space Fence program is developing a system of large ground-based radars that will replace the Air Force Space Surveillance System, which became operational in 1961 and was recently shut down. Space Fence will use higher radio frequencies to detect and track more and smaller earth-orbiting objects than is currently possible. The Air Force currently plans to award a contract for construction of one radar with an option for a second.

Total quantities	NA	1	NA
Acquisition cycle time (months)	NA	116	NA

The Space Fence program has seven critical technologies, which are expected to demonstrate full maturity during or after the critical design review. The program delayed development start and awarding of the system development contract to May 2014, a delay of almost 2 years. As a result, the program delayed initial operational capability by a year to November 2018. DOD budget reductions also led to the early shutdown of the Air Force Space Surveillance System, which was originally planned to be operational through Space Fence's initial operations. A new data processing system is being developed by the Air Force, separate from Space Fence, to accommodate the projected increase in the volume of data generated.

4161 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Space Fence Program

Technology Maturity

All seven of the program's critical technologies are currently nearing full maturity and are not expected to demonstrate full maturity until the critical design review, scheduled for 9 months after development start, or later. According to program officials, the critical technologies are not particularly challenging advances in technology. The risk for the program is in deploying radars on the very large scale needed. The program's technology development phase included competitive development of two fully working prototypes by separate contractors to reduce program risk. If a second radar site is deemed necessary, the technologies used for that site may differ, depending on the final program design.

Design and Production Maturity

The contract for the final Space Fence system development contract has not yet been awarded, so the program does not have a final system design and thus we did not assess design or production maturity.

Other Program Issues

The Air Force plans to competitively award a single system development and production contract in May 2014. This date reflects the second significant delay to contract award from the original date of July 2012. The first delay was due to an internal DOD program review required before the contract proposal could be issued. The program office attributes the additional delay in awarding the contract and initiating development to the strategic choices management review, which looked at affordability of future acquisitions DOD-wide.

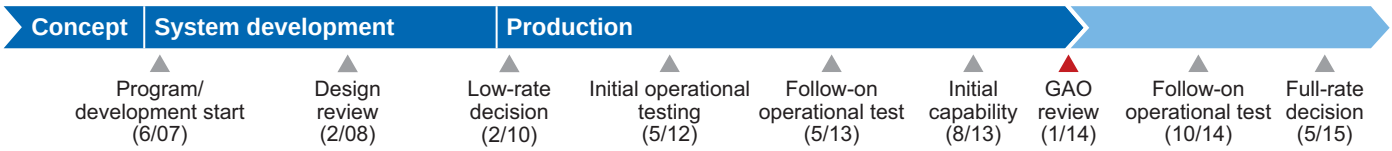
The Air Force plans to award a fixed-price incentive contract for system development activities for the first radar site, with a contract option for the second site. If the option for the second site is exercised, it is planned to be operational 36 months after the program meets initial operational capability. However, funding for the second site is uncertain, and it potentially may not be needed depending on whether the first site exceeds its design capability. Program officials stated that the decision on whether or not to build a second site will likely be made after the first site is operational. In addition, the program has pushed back the anticipated initial operational capability date by more than a year, to 2018.

The Air Force Space Surveillance System, the legacy system that Space Fence will replace, ended operations in October 2013. The Air Force originally intended to keep that system functioning until Space Fence became operational. According to the Air Force, the decision to end operations early was made due to funding constraints caused by sequestration. Air Force officials said they have modified the operations of other space surveillance assets in a way that will maintain a roughly equivalent level of space surveillance until Space Fence is operational.

The Joint Space Operations Center (JSpOC) at Vandenberg AFB is acquiring a new data processing capability—JSpOC Mission System (JMS)—to process the increased volume of data expected from Space Fence. JMS is being developed through a separate acquisition program and, according to Space Fence program officials, is required to process the amount of data Space Fence is expected to generate. Currently, JMS is scheduled to become operational by December 2016, enabling input and processing of data from Space Fence in time for its initial operational capability.

Program Office Comments

In commenting on a draft of this assessment, the program office noted that the Office of the Secretary of Defense chose to delay the Space Fence system development certification in light of the strategic choices Management review outcomes. The Air Force amended the Space Fence request for proposals issued in November 2013. This amendment reflects the change to the initial operational capability delivery date, specified as 56 months after contract award (first quarter fiscal year 2019), as well as a full operational capability date, specified as 36 months after initial operational capability (first quarter fiscal year 2022). It also reflects an update to the total projected budget to more closely reflect the current fiscal reality. Having resumed source selection, award of a single fixed price incentive contract is expected in the third quarter of fiscal year 2014. The program also provided technical comments, which were incorporated where appropriate.



4162 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Warfighter Information Network-Tactical Increment 2 (WIN-T Inc 2)

WIN-T is the Army's high-speed and high-capacity backbone communications network. It connects units with higher levels of command and provides the Army's tactical portion of the Global Information Grid. WIN-T was restructured following a March 2007 Nunn-McCurdy unit-cost breach of the critical threshold, and will be fielded in four increments. We assessed the second increment, which is expected to provide the Army with an initial networking on-the-move capability.

Program office: Aberdeen Proving Ground, MD
Funding needed to complete:
R&D: $22.3 million
Procurement: $2,285.1 million
Total funding: $2,307.3 million
Procurement quantity: 661

Program Performance (fiscal year 2014 dollars in millions)

	As of 10/2007	Latest 08/2013	Percent change
Research and development cost	$250.9	$296.6	18.2
Procurement cost	$3,649.2	$4,749.6	30.2
Total program cost	$3,900.2	$5,046.2	29.4
Program unit cost	$2.060	$2.341	13.6
Total quantities	1,893	2,156	13.9
Acquisition cycle time (months)	50	74	48.0

The Army was directed in September 2013 to update the cost position and program baseline. These changes are not reflected in the latest column above.

WIN-T Increment 2 entered production in February 2010 with mature critical technologies and, according to program office metrics, a stable design, but before bringing manufacturing processes under control. A recent assessment of the program's manufacturing readiness levels indicates that these processes are now demonstrated and under control as the program approaches full rate production. However, during its May 2012 initial operational test, the program did not demonstrate required performance and reliability. A follow-on operational test in May 2013 showed improved reliability and performance but revealed that deficiencies remain. Consequently, the milestone decision authority has delayed the full rate production decision until the Army completes an additional follow-on operational test and confirms that deficiencies have been corrected.

4163 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

WIN-T Increment 2 Program

Technology Maturity

All 15 WIN-T Increment 2 critical technologies were mature by its February 2010 production decision. In August 2012, an independent manufacturing readiness assessment prepared by the Army concluded that the prime contractor had achieved an acceptable level of technology maturity to continue to full rate production.

Design Maturity

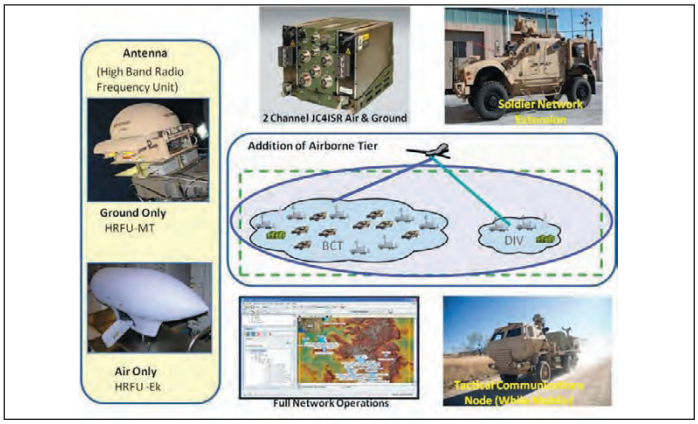
According to the WIN-T program, it has integrated and tested its key technologies and subsystems to demonstrate that the system's design is capable of working as intended. The program office does not track the metric we use to measure design maturity—the number of releasable drawings—as WIN-T is primarily an information technology integration effort. Instead, design performance is measured through a series of component, subsystem, configuration item, and network-level tests designed to demonstrate performance at increasing levels of system integration. Design stability is measured through problem-tracking report trends.

Production Maturity

The WIN-T Increment 2 program began production in February 2010 and began testing a production-representative prototype 13 months later in March 2011. The program indicates that its manufacturing processes—as determined by an Army manufacturing readiness assessment—are now in control, but had not yet been demonstrated or brought in control at production start. During its May 2012 initial operational test, the program did not demonstrate required performance and reliability. A follow-on operational test in May 2013 showed improved reliability and performance but revealed that deficiencies remain. In particular, three of the program's nine configuration items were assessed as not operationally effective and two were not operationally suitable due to complexity of operations and reliability problems. In addition, the program demonstrated cyber security vulnerabilities that need improvement. Consequently, the milestone decision authority has delayed a full rate production decision until the Army completes an additional follow-on operational test in November 2014 as part of the Army's Network Integration Evaluation 15.1 that confirms that deficiencies have been corrected. A full-rate production decision is planned for May 2015.

Other Program Issues

While the milestone decision authority has not yet approved a full-rate production decision, the Army declared that the program attained its initial capability in August 2013. This decision was based on the Army's assertion that initial operational capability was reached when the first brigade combat team and its division headquarters was equipped and fully trained with the new equipment and the follow on operational test had been successfully completed. However, as noted above, the May 2013 follow-on operational test revealed deficiencies with the program that must be corrected and these corrections must be confirmed during an additional follow-on operational test.



Program Office Comments

In commenting on a draft of this assessment, the Army noted that in September 2013, it received approval from the Defense Acquisition Board for an additional low-rate initial production lot and an acceptance to field existing lots of WIN-T Increment 2. The Army has fielded five Brigade Combat Teams and two divisions, and remains on track to field Capability Set 14 to units, including Stryker Brigade Combat Teams. Using soldier feedback from theater and test results, the Army intends to continue to improve WIN-T Increment 2 capabilities with the primary focus being on simplifying the operations and maintenance of the equipment. The program office also provided technical comments, which were incorporated where deemed appropriate.

4164 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Warfighter Information Network-Tactical Increment 3 (WIN-T Inc 3)

WIN-T is the Army's high-speed and high-capacity backbone communications network. It connects units with higher levels of command and provides the Army's tactical portion of the Global Information Grid. WIN-T was restructured following a March 2007 Nunn-McCurdy unit-cost breach of the critical threshold, and will be fielded in four increments. We assessed the third increment, which is expected to provide the Army a full networking on-the-move capability.

Acquisition cycle time (months)	165	199	20.6

The Army is restructuring the program. Changes to the program's costs, quantities, and schedule from this restructuring are not reflected in the latest column above.

According to an Army representative, 12 of WIN-T Increment 3's 18 current critical technologies are mature and 6 are nearing maturity following the critical design review of the program in December 2013. However, the program is being restructured based on the recommendations of a configuration steering board held in November 2013. This restructuring could affect the program's need for certain critical technologies. The program does not use the number of design drawings released or alternative methods to assess design stability. However, the program plans to begin capturing software design stability metrics once a baseline system design is established.

4165 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

WIN-T Increment 3 Program

Technology Maturity

According to an Army representative, 12 of the program's 18 current critical technologies are mature, and 6 are nearing maturity following the critical design review of the program in December 2013. However, in January 2014 the Army acquisition executive directed the program executive officer with oversight of the WIN-T Increment 3 program to restructure the program based on the recommendations of the Army's configuration steering board.

The program's restructuring could affect its need for certain critical technologies. For example, the Army's configuration steering board has recommended descoping the air tier from the program. According to an Army representative, the program will need to complete a follow-on critical design review once it has been restructured, at which point the critical technologies will need to be reassessed.

Design Maturity

The program does not use the number of design drawings released or any alternative methods to assess design stability. According to the program office, the number of design drawings is not meaningful as WIN-T is not a manufacturing effort, but a software development and hardware integration effort. The program asserts that it has appropriate software metrics and tracks design stability through its configuration management software production plan.

Other Program Issues

According to an Army representative, the Army is in the process of conducting a "network capability" review to determine the "right mix"of tactical networking capabilities to provide to brigade combat teams. In addition, the program is awaiting the final assessments from the Army's recently completed configuration steering board. These two events will factor into the scope of the restructured program. According to an Army representative, restructuring considerations may include maximizing the use of the capabilities currently being fielded under the WIN-T Increment 2 program while maintaining focus on WIN-T Increment 3 network operations efforts and balancing affordability, as DOD and the Army face long-term budgetary challenges.

Program Office Comments

In commenting on a draft of this assessment, the Army noted that as of early 2014, the WIN-T Increment 3 program is anticipating a final program assessment from the Department following the program's critical design review and is also awaiting Department's approval of a program transition strategy based on the WIN-T Increment 3 configuration steering board meeting held in November 2013. These events, coupled with ongoing Army tactical network capability review decisions, will provide guidance on the scope of the program's effort going forward.

4166 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Airborne and Maritime/Fixed Station Joint Tactical Radio System (AMF JTRS)

The Army's AMF JTRS program plans to acquire two non-developmental software-defined radios, the Small Airborne Link 16 Terminal (SALT) and the Small Airborne Networking Radio (SANR), and associated equipment for integration into Army rotary wing and unmanned aerial systems. Previously, the program had been developing software-defined radios and associated equipment for integration into nearly 160 different types of aircraft, ships, and fixed stations to increase communications and networking capabilities.

Source: U.S. Army.

Current Status

The Under Secretary of Defense for Acquisition, Technology, and Logistics, in July 2012, restructured the AMF JTRS program due to concerns about the potential for unbounded cost increases, and continued schedule and contractor performance risk. Market research also determined that non-developmental items could be modified to meet users' revised needs and priorities. The Under Secretary also transferred responsibility for program management to the Army. While the use of a non-developmental item approach will likely reduce some technical risk, the Army will need to manage the integration of government-developed waveforms into the non-developmental item radios and the radios into various platforms.

AMF JTRS now plans to acquire two non-developmental software-defined radios. The SALT is designed to be a 2-channel radio capable of running the Link 16 waveform and the Soldier Radio Waveform (SRW). The program plans to introduce production hardware into the Apache AH-64E assembly line in fiscal year 2016. Until then, according to program officials, the Apache program office is pursuing an interim solution, the Small Tactical Terminal (STT), which will run only Link 16. The Army acquisition strategy for SALT calls for full and open competition. The Army plans to release the SALT request for proposals in the second quarter of fiscal year 2014 and a full rate production decision is scheduled for fiscal year 2016.

The SANR is designed as a 2-channel radio capable of running the SRW, Single Channel Ground and Airborne Radio System waveform, and the Wideband Networking Waveform. The SANR acquisition strategy plans a full and open competition to select two contractors for SANR test assets. A low rate initial production decision is scheduled for fiscal year 2016 and full rate production is scheduled for fiscal year 2018.

Estimated Program Cost and Quantity (fiscal year 2014 dollars):
Total program: $3,582.7 million
Research and development: $1,849.3 million
Procurement: $1,733.4 million
Quantity: 15,652 channels

Next Major Program Event: SALT full-rate production and SANR low-rate initial production decisions in first quarter 2016.

Program Office Comments: The program office concurred with the assessment.

4167 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Amphibious Combat Vehicle (ACV)

The Marine Corps' ACV is intended to transport troops from ship to shore and secure a beachhead. The Marine Corps has a requirement to replace the existing amphibious assault vehicle (AAV) but the Secretary of Defense terminated the initial effort, the Expeditionary Fighting Vehicle (EFV) program, in January 2011 due to technology problems, development delays, and cost increases.

Source: U.S. Marine Corps.

Current Status

A December 2011 materiel development decision memorandum directed that a "highly tailored" approach be used to acquire the ACV and that this effort focus on a cost-effective solution, emphasizing engineering and design analysis through establishment of affordability targets. According to officials, the Marine Corps completed an ACV analysis of alternatives (AOA) in July 2012 and the Navy forwarded it to the Office of the Secretary of Defense. According to ACV program officials, although high-water speed had been a primary requirement for the EFV, it was not part of the initial ACV AOA study. Instead, the study was based on a speed requirement that was about half of the EFV's, which would make the ACV a "displacement" vehicle more similar in water speed to the AAV. Marine Corps leadership subsequently directed that the affordability of a high-water speed amphibious vehicle be studied before the ACV began acquisition. This feasibility analysis is ongoing.

Officials reported that the Marine Corps is studying trade-offs in ACV capability to find the ACV design that will provide improvements in amphibious capability-speed, range, lethality, and survivability-over the current amphibious vehicle at an affordable cost. They added that, following the feasibility analysis, the Marine Corps Commandant will make a decision on whether the ACV acquisition program will formally begin at technology development or system development. Expectations are that the ACV will not reach initial operating capability before 2023. To address the delay in fielding an amphibious vehicle to replace the legacy AAVs, 392 current AAVs will undergo survivability upgrades that will address deficiencies in survivability.

Estimated Program Cost and Quantity (fiscal year 2014 dollars):
Total program: TBD
Research and development (fiscal years 2012-2017): $1,047.1 million
Procurement: TBD
Acquisition related operation and maintenance (fiscal years 2012-2017): $18.9 million
Quantity: TBD

Next Major Program Event: System development start, TBD

Program Office Comments: The Marine Corps was provided a draft of this assessment and did not offer any comments.

4168 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Armored Multi-Purpose Vehicle (AMPV)

The Army's Armored Multi-Purpose Vehicle (AMPV) fleet is the proposed replacement to the M113 family of vehicles in the armored brigade combat team. The AMPV will replace the M113 in five mission roles: general purpose, medical evacuation, medical treatment, mortar carrier, and mission command. The Army has determined that development of the AMPV is necessary due to mobility deficiencies identified in the M113, as well as space, weight, power and cooling limitations that prevent the incorporation of future technologies.

Source: U.S. Armv.

Current Status

Based on direction at the August and November 2013 defense acquisition board reviews, AMPV's acquisition strategy was updated and approved before a request for proposals was released in November 2013. The program's acquisition strategy is based on modifying an existing platform and bypasses the technology development phase to begin in system development. The program is still working to define key technologies, and as a result, will require potential contractors to include data related to the technology maturity of their design in each proposal. AMPV's acquisition strategy also calls for selection of a single contractor for system development, and provides for three low-rate initial production options within the system development contract. The program currently plans to award a cost plus incentive fee contract for system development with a fixed price incentive option for low-rate initial production. The AMPV contract will include engineering and manufacturing development and low-rate initial production incentives for cost and reliability.

Procurement of AMPV, with an estimated total acquisition cost of up to $10.2 billion, will occur at about the same time as the Army's Joint Light Tactical Vehicle program. The procurement of these programs is expected to continue for a decade or more.

Estimated Total Program Cost and Quantity (fiscal year 2014 dollars)
Total Program: $10,223 million
Research and development: $779.9 million
Procurement: $9,443.0 million
Quantity: 2,907

Next Major Program Event: Start of system development, first quarter fiscal year 2015

Program Office Comments: In commenting on a draft of this assessment, the program office provided technical comments, which were incorporated where deemed appropriate.

4169 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

B-2 Defensive Management System Modernization (B-2 DMS)

The Air Force's B-2 DMS modernization program is expected to upgrade the aircraft's analog defensive management system to a digital capability to detect, identify and avoid threats. The modernization is intended to update pilot displays and enhance the in-flight capability to avoid unanticipated air defense threats. Improvement in frequency coverage, sensitivity of the electronic warfare suite, and reliability and maintainability are also anticipated. The latter is expected to improve the B-2's readiness rate.

Source: U.S. Air Force.

Current Status

In October 2012, the program entered a second technology development phase, which continued throughout 2013. The program had scheduled a preliminary design review prior to beginning system development in April 2014, but officials told us they are currently restructuring the program due to expected future budget reductions. Program documentation indicates moderate technical risk due to the program's schedule and nuclear hardening activities. Also, the antenna design, the software schedule, and the availability of test aircraft are risk areas. Early in the program, an independent assessment identified six critical technologies; however, currently the program does not believe any critical technologies exist. Another independent technology readiness assessment, scheduled prior to system development, will identify the final list of critical technologies.

We have previously reported that the program was implementing a rapid acquisition initiative to reduce its acquisition time by up to 3 years and lower costs by as much as $500 million. To achieve these results, several activities were planned including: early software prototyping, reducing the time required for flight testing, and improving antenna installation times. By conducting these activities, it was anticipated the program might take 7 years to complete and cost $1.58 billion. While some parts of the initiative have yielded positive results, including a subcontractor competition for antenna development that officials told us saved time and money, the program's start of development, flight testing, and full operational capability have all been delayed. The program now expects to complete acquisition in almost 9 years at a cost of over $2 billion, which means most of the expected reductions in cost and schedule from the initiative will not be realized.

Estimated Program Cost and Quantity (fiscal year 2014 dollars):
Total program: $2,036 million
Research and development: $1,385 million
Procurement: $651 million
Quantity: 20

Next Major Program Event: System development start, April 2014

Program Office Comments: In commenting on a draft of this assessment, DOD officials told us the assessment is accurate based on the fiscal year 2014 budget. They added that the B-2 DMS modernization program remains the top B-2 modernization priority. The program office also provided technical comments which were incorporated as appropriate.

4170 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Combat Rescue Helicopter (CRH)

The Air Force's Combat Rescue Helicopter (CRH) program, formerly called HH-60 Recapitalization, is an effort to replace aging HH-60G Pave Hawk helicopters. The CRH's primary mission is to recover personnel from hostile or denied territory; it will also conduct humanitarian, civil search and rescue, disaster relief, and non-combatant evacuation missions. The program is the second effort to replace the HH-60G. The first, the Combat Search and Rescue Replacement Vehicle (CSAR-X), was canceled because of cost concerns in 2009.

Source: 2013 Sikorsky Aircraft Corp. Used with permission for support of CRH.

Current Status

The Air Force expects that the CRH will be an existing helicopter with modifications to integrate mature technology subsystems and associated software. The CRH program received its materiel development decision in March 2012 and DOD authorized the program to bypass technology development and enter the acquisition process at system development. The program successfully completed a defense acquisition board review in September 2012 which approved its acquisition strategy and release of a request for proposals for a full and open competition in October 2012. Depending upon the availability of future funding, the CRH program office plans to enter system development in March 2014, delayed from the originally scheduled August 2013. The program is preparing to then award a fixed price incentive firm target development contract to Sikorsky, which was the only contractor who responded to the request for proposals. However, the program does not intend to conduct any systems engineering technical reviews until after the development contract is awarded. According to officials from the Office of the Secretary of Defense, the program was granted a waiver in late 2012 to conduct its preliminary design review after the start of system development, as well as a waiver for the requirement to conduct competitive prototyping. In our previous work, we have found that acquisition programs which successfully complete robust systems engineering early in the acquisition process and conduct a preliminary design review prior to starting system development typically have better outcomes. Initial operational capability for the helicopter is expected in the fourth quarter of fiscal year 2019.

Estimated Total Program Cost (fiscal year 2014 dollars):
Total program: TBD
Research and development (fiscal years 2012-2018): $1,310.9 million
Procurement (fiscal years 2016-2018): $ 2,187.7 million
Military construction: TBD
Acquisition operations and maintenance: TBD
Total quantity: 112

Next Major Program Event: System development start, March 2014

Program Office Comments: In commenting on a draft of this assessment, the program office provided technical comments, which were incorporated where deemed appropriate.

4171 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Common Infrared Countermeasure (CIRCM)

The Army's CIRCM, the next generation of the Advanced Threat Infrared Countermeasures (ATIRCM), will be used with a missile warning system and a countermeasure dispenser capable of employing expendables, such as flares and chaff, to defend aircraft from infrared-guided missiles. The CIRCM program will develop a laser-based countermeasure system for rotary-wing, tilt-rotor, and small fixed-wing aircraft across DOD. CIRCM is one of three subprograms that make up the ATIRCM/CMWS major defense acquisition program.

Sources: © 2011 BAE Systems (left); Northrop Grumman (right)

Current Status

The CIRCM program began in 2009 when the Under Secretary of Defense for Acquisition, Technology and Logistics supported the Army's decision to restructure the ATIRCM/CMWS program. In June 2009, the Army received approval to award five contracts to provide prototype systems for testing. After testing these prototypes, the Army concluded that the systems were not mature enough for entry into system development. The Army subsequently decided that the program should proceed with a technology development phase that will include additional prototyping efforts to further mature CIRCM technologies and awarded two contracts in January 2012.

The Army held preliminary design reviews in July and August, 2013 with both contractors. The review report stated that the system's preliminary design satisfies the operational and suitability requirements. Also, the Army recently conducted a preliminary technology readiness assessment based on contractor testing in which nine critical technology elements were identified and are approaching full maturity leading up to system development. A final technology readiness assessment will be conducted prior to development to verify technology and design maturity and will be based on government-witnessed testing.

In October 2013, the two CIRCM contractors completed prototypes deliveries. According to the Army, both designs are mature and are low risk of not meeting the specified requirements even with the current configurations. The Army plans to make a system development decision in December 2014 and plans to award one contractor a cost plus fixed fee/firm fixed price contract with technical performance incentives focused on achievement of weight and reliability goals.

Estimated Program Cost and Quantity (fiscal year 2014 dollars):
Total Program: $3,599.8 million
Research and development: $788.8 million
Procurement: $2,811.0 million
Quantity: 1,076

Next Major Program Event: System development start, December 2014

Program Office Comments: In commenting on a draft of this assessment, the program office provided technical comments, which were incorporated where deemed appropriate.

4172 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

DDG 51 Destroyer (DDG 51)

The DDG 51 destroyer is a multimission ship designed to operate against air, surface, and subsurface threats. After a nearly 4-year break, the Navy restarted Flight IIA production and plans to buy at least nine ships between fiscal years 2013 and 2017. The Navy plans to procure three Flight III ships, a modification of the Flight IIA design, beginning in fiscal year 2016. Flight III is expected to have an increased focus on missile defense and will include the Air and Missile Defense Radar (AMDR), initially an S-band radar developed under a separate program.

Source: Bath Iron Works.

Current Status

Four DDG 51 Flight IIA ships are under construction and an additional nine ships are under contract. The design of the Flight IIA ships will be modified to include an upgraded Aegis combat system currently being developed. The Navy will also replace the existing SPS-67 radar with SPQ-9B, currently installed on several Navy ships, beginning in fiscal year 2014. The Navy believes that it has largely resolved issues with production of a new reduction gear.

DDG 51 Flight III ships are expected to feature new electric plants, new air-conditioning plants, and the AMDR. According to the Navy, the new electric plants are based on a design used on DDG 1000 and modification will be required for integration with DDG 51. The DDG 1000 electrical system has faced delays in completing testing. Detail design work for Flight III will begin at the end of fiscal year 2014, according to the Navy. Adding AMDR to DDG 51 will result in a significant redesign of the ship and the Navy expects that Flight III will result in changes to more than 25 percent of Flight IIA drawings, although the Navy believes many of these will be minor alterations. The Navy will need AMDR's design assumptions, such as its size, shape, weight, and power and cooling requirements in order to accurately redesign the ship. However, the Navy only recently awarded a contract for AMDR system development and the AMDR program is at least 6 months behind schedule. Based on its current schedule, the Navy plans to begin detail design work for Flight III at the end of fiscal year 2014—before AMDR has demonstrated full maturity-adding risk and uncertainty to the DDG 51 program.

Estimated Program Cost and Quantity (fiscal year 2014 dollars):
Total program (fiscal years 2010 to 2018): $23,089.5 million
Research and development (fiscal years 2010 to 2018): $900 million
Procurement (fiscal years 2010 to 2018): $22,189.6 million
Quantity: 15

Next Major Program Event: Defense acquisition board review of Flight III modifications, third quarter fiscal year 2014.

Program Office Comments: According to program officials, the Flight III schedule integrates all equipment development efforts into the overall ship detail design effort. This is the same process successfully implemented on previous flight upgrades. Due to the AMDR technology development phase, which produced working 1000-element arrays, the current design maturity supports commencement of detail design. Flight III is on track to be implemented on the second fiscal year 2016 ship.

4173 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

F-15 Eagle Passive/Active Warning and Survivability System (F-15 EPAWSS)

The Air Force's F-15 EPAWSS program is intended to upgrade the electronic warfare system on fielded F-15 aircraft. The program seeks to improve the aircraft's internal self-protection electronic warfare systems to enable operations in current and future threat environments. The program is also expected to improve the F-15's survivability by enhancing its ability to detect, identify, locate, deny, degrade, disrupt, and defeat air and ground threat systems.

Source: U.S. Air Force.

Current Status

In November 2012, the Office of the Under Secretary of Defense for Acquisition, Technology, and Logistics approved the Air Force's plans to conduct an analysis of alternatives and to award a pre-engineering and manufacturing development characterization contract for the F-15 EPAWSS program, which occurred in fiscal year 2013. The Air Force plans to leverage non-developmental electronic warfare technologies and components, currently used in other Air Force and Navy aircraft, to create a state-of-the-art wide bandwidth digital electronic warfare system capable of protecting the F-15 aircraft against advanced enemy threats. The Air Force is currently updating the program's requirements documentation and intends to conduct a preliminary design review before starting system development in fiscal year 2016. The program office plans to award a production contract in fiscal year 2018.

An early Air Force assessment of F-15 EPAWSS identified digital receiver technology—both the hardware and the associated software—as a critical technology that the program does not intend to fully mature prior to the start of system development. According to program officials, a key risk is integration of the electronic warfare system with all other on-board and off-board systems, so that it operates properly in its intended operational environment. The program expects to add future capabilities as new electronic warfare threats emerge.

Estimated Program Cost and Quantity (fiscal year 2014 dollars):
Total program: TBD
Research and development: $614.9 million (fiscal years 2014 to 2018)
Procurement: TBD
Quantity: 392

Next Major Program Event: Defense acquisition board review of acquisition strategy, February 2014

Program Office Comments: According to the Air Force, the program office continues to refine the planning for the F-15 EPAWSS program based on in-work requirements documentation and final acquisition strategy approval by the Milestone Decision Authority.

.

4174 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Ground Combat Vehicle (GCV)

The Ground Combat Vehicle (GCV) is an incremental program to replace segments of the Army's combat vehicle inventory. The first variant is intended to be the service's next infantry fighting vehicle, replacing a portion of the current M2 Bradley fleet. The Army expects GCV to provide a full-spectrum capability to perform offensive, defensive, stability, and support operations; carry a nine-soldier squad; emphasize force protection; and be operational within 7 years of beginning technology development.

Source: U.S. Army.

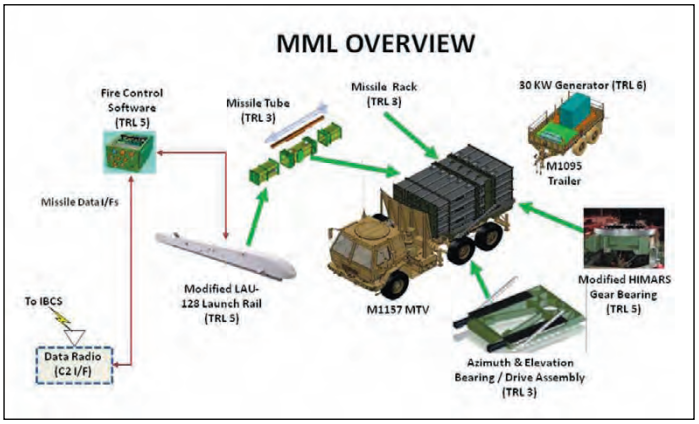
Current Status

In August 2011, the Under Secretary of Defense for Acquisition, Technology, and Logistics approved GCV's entry into technology development. The Army awarded contracts to two contractor teams, but resolving a bid protest prevented the start of technology development until December 2011. Since then, the Army has been involved in three activities: updating the analysis of alternatives, assessing upgrades to existing vehicles, and funding two contractors' efforts to build and demonstrate key subsystem prototypes.

On January 16, 2013, the Under Secretary directed a number of changes to the program, including extending the technology development phase six months, delaying both system development and production, and directing that a single prime contractor be selected for system development. These actions provide significant reductions to the funding necessary to execute the program.

An independent review team identified three candidate critical technologies—all nearing full maturity—that could be incorporated into the GCV design. The program will continue monitoring these technologies and consider their maturity and risk as part of the full and open competition planned for system development. Since our last report, both contractors continued technology development by maturing preliminary designs and subsystems, completing multiple tests of their respective mine blast protection designs, and testing engines and drive trains. After holding preliminary design reviews to determine whether the proposed designs could satisfy requirements, a defense acquisition board will determine the program's readiness to proceed into system development, which is expected to begin in June 2014.The Army plans to begin procuring GCV while simultaneously procuring other new and costly combat vehicles including the Joint Light Tactical Vehicle.

Estimated Program Cost and Quantity (fiscal year 2014 dollars):
Total program: $29,219.6 million
Research and development: $4,968.5 million
Procurement: $24,229.1 million
Quantity: 12 (development), 1,874 (procurement)



Next Major Program Event: System development start, June 2014

Program Office Comments: According to officials in the office of the Under Secretary of Defense for Acquisition, Technology, and Logistics, the GCV program was cancelled on the order of the Secretary of Defense.

4175 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Indirect Fire Protection Capability-Increment 2 (IFPC Inc 2)

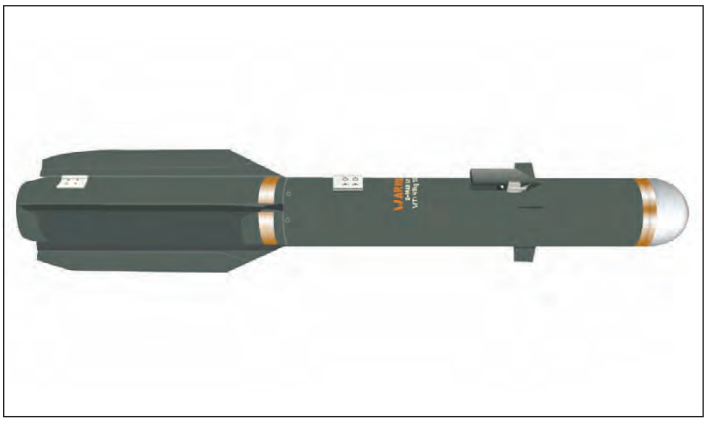
The Army's IFPC Increment 2 consists of three blocks, each a separate major defense acquisition program, to detect, assess, and defend against threats from rockets, artillery, mortars, cruise missiles, and unmanned aircraft. The first IFPC increment, fielded in 2004, provides a short-range capability to counter rockets, artillery, and mortar threats. IFPC Increment 2, Block 1 establishes the capability to counter cruise missiles and unmanned aircraft. The remaining blocks add to and extend the range and capability.

Source: U.S. Army.

Current Status

In 2004, after the first increment of IFPC was fielded, users developed a new requirement to counter unmanned aircraft and cruise missiles. The Surface Launched Advanced Medium-Range Air-to-Air Missile was originally set to fulfill this requirement, but was cancelled. To replace it, in 2011, the Army proposed a new interceptor, launcher, and radar. The $1.6 billion estimate for developing this new system, however, was deemed unaffordable. The Army then proposed a three block alternative, each a separate major defense acquisition program, which leverages an existing interceptor and sensor and competitively awards the development of a new launcher. Block 1 is scheduled for fielding in fiscal year 2019. The review to begin technology development for Block 1 was held October 22, 2013, but final approval is pending until January 2014 due to budget concerns, including sequestration, according to officials. Program officials noted that the most significant risk is integration with the existing systems being leveraged, such as the AIM 9 Class Interceptor and the Sentinel radar. Successful integration is necessary to avoid increased costs or overall failure to meet requirements. According to program officials, the program is reusing existing technologies to promote affordability and using open systems architecture for the launcher to enable it to work with a variety of current and future missiles. Blocks 2 and 3 are scheduled to begin development in fiscal years 2019 and 2027, respectively.

Estimated Program Cost and Quantity (fiscal year 2014 dollars):
Total program: $2.5 billion
Research and development: $510 million
Procurement: $2.0 billion
Quantity: 5 (development), 344 (procurement)



Next Major Program Event: System requirement review, January 2014

Program Office Comments: In commenting on a draft of this assessment, the program office provided technical comments, which were incorporated where deemed appropriate.

4176 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Joint Air-to-Ground Missile (JAGM)

The Joint Air-to-Ground missile is an Army-led program with joint requirements from the Navy and Marine Corps. The missile is designed to be air-launched from helicopters and unmanned aircraft systems to target tanks; light armored vehicles; missile launchers; command, control, and communications vehicles; bunkers; and buildings. It is intended to provide line-of-sight and beyond line-of-sight capabilities and deploy in a fire-and-forget mode or a precision attack mode. JAGM will replace all variants of HELLFIRE missiles.

Source: U.S. Army.

Current Status

In early 2012, the Army restructured JAGM extending technology development by more than 2 years to explore evolutionary alternatives to the acquisition strategy, refine requirements and explore a more affordable solution. In August and November 2012, the Army awarded letter contracts to Lockheed Martin and Raytheon for this extended technology development. Program officials stated that these efforts focus on the guidance section, the key technology that provides the capabilities required by the Army, Marine Corps, and Navy. Preliminary design reviews of each contractor's design were held in February and April 2013, respectively.

The Assistant Secretary of the Army for Acquisition, Technology, and Logistics conducted a program status review informed by the preliminary design reviews to assess the program's cost, schedule, and performance risk. Based on funding shortfalls of $36 million and findings of the risk assessment, in August 2013, the Assistant Secretary of the Army for Acquisition, Technology, and Logistics directed the JAGM program to execute the continued technology development phase with a single contractor in order to meet technology development objectives on schedule. According to program officials, Raytheon's technical performance was not on track to meet program goals or Army requirements. As a result, the government did not award a follow-on contract to extend performance after April 2013. Lockheed Martin will continue with technology development under their existing contract. Upon completion of all objectives and technology development exit criteria, approval of the acquisition strategy, and completion of the source selection evaluation board, the Army is planning for a system development decision in fiscal year 2015. The acquisition strategy will allow for a competitive contract award for system development.

Estimated Total Program Cost and Quantity (fiscal year 2014 dollars):
Total Program: TBD
Research and development (fiscal years 2008-2018): $656.4 million
Procurement (fiscal years 2008 to 2018): $116.8 million
Quantity: 167

Next Major Program Event: Subcomponent critical design review, January 2014

Program Office Comments: In commenting on a draft of this assessment, the program office provided technical comments, which were incorporated where deemed appropriate.

4177 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Joint Land Attack Cruise Missile Defense Elevated Netted Sensor System (JLENS)

The Army's JLENS is designed to provide elevated, persistent, over-the-horizon surveillance and fire control quality data enabling protection of U.S. and coalition forces and critical assets. A JLENS orbit consists of two systems: a fire control radar system and a surveillance radar system. Each system is comprised of a 74-meter tethered aerostat, a mobile mooring station, communication and processing stations, and ground support equipment. The program was restructured following a Nunn-McCurdy unit-cost breach of the critical threshold.

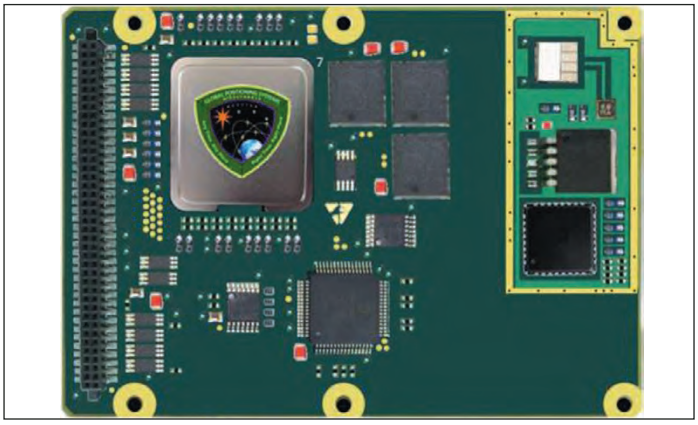
Source: U.S. Army.

Current Status

In August 2013, the Under Secretary of Defense for Acquisition, Technology, and Logistics approved the program's revised acquisition program baseline, re-designated the program's acquisition category and delegated milestone decision authority to the Secretary of the Army. The JLENS program satisfied developmental testing and evaluation requirements and is proceeding with plans to execute a 3-year operational combatant command exercise. The exercise is expected to demonstrate JLENS capabilities for homeland defense and inform a future decision for enduring operational employment.

The program reported that recent operational test events at the Utah Test and Training Range and at the White Sands Missile Range demonstrate that JLENS performs as expected. Phase two of the second early user test—which assessed system performance and reliability and allowed for soldier training on system configuration—was successfully completed in June 2013, and, according to program officials, eliminated the need for the third series of developmental tests. Integrated fire control testing occurred in July 2013 and demonstrated JLENS capabilities in acquiring, tracking and providing sensor track data. The program will need to complete "friend or foe" identification system and communication link certification events before it can participate in the exercise. Site construction for the deployment of the exercise will begin at Aberdeen Proving Ground after the February 2014 construction contract award. The construction will involve completing aerostat pads, roads, operation and support facilities, and infrastructure. The initial system is expected to arrive at the exercise site location in June 2014 and initial capability delivery is expected for the surveillance radar in September 2014 and the fire control radar system in December 2014.

Estimated Program Cost and Quantity (fiscal year 2014 dollars):
Total program: $2,782.12 million
Research and development: $2,741.61 million
Military construction: $40.51 million
Quantity: 2



Next Major Program Event: February 2014 construction contract award for exercise site construction.

Program Office Comments: In commenting on a draft of this assessment, the program office provided technical comments, which were incorporated where deemed appropriate.

4178 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Military GPS User Equipment (MGUE), Increment 1

The Air Force's MGUE program plans to develop GPS receivers compatible with the military's next-generation GPS signal, Military-Code. The modernized receivers are to provide U.S. forces with enhanced position, navigation, and time capabilities, while improving resistance to existing and emerging threats, such as jamming. The program is to be completed in two increments. Increment 1, assessed here, leverages technologies from the Modernized User Equipment (MUE) program to develop two variants and begin development of the Common GPS Module.

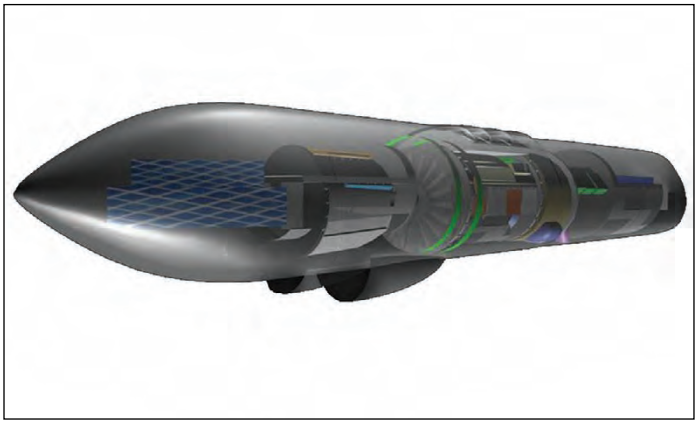
Source: U.S. Air Force.

Current Status

In April 2012, the Air Force initiated technology development for Increment 1 of MGUE. According to the Air Force, all five critical technologies identified by the Office of the Secretary of Defense—military-code acquisition engine, military-code cryptography, selective availability/anti-spoofing module cryptography, anti-spoofing, and anti-tamper-are currently nearing maturity. The Air Force plans to develop two variants—one each for ground and aviation, as Navy officials believe the aviation variant can support maritime needs. The current approved Increment 1 program leverages technologies from the Modernized User Equipment program to develop two variants and begin development of the Common GPS Module. Increment 2 is not yet approved.

The program's preliminary design review has been delayed 5 months, to June 2014. According to officials, the delay was caused by two factors: sequestration of fiscal year 2013 MGUE funding, which forced the program to limit contractor activity, and a new initiative to reduce complexity within the cryptography required to encrypt and decrypt communications. In last year's assessment, the program reported two main risk areas, ensuring more than one contractor meets design requirements for the application specific integrated circuit (ASIC)—a vital component leveraged from MUE—and software development. According to Air Force officials, progress in manufacturing and testing the ASIC as well as the complexity reduction effort has largely addressed these risk areas. However, the program identified a new risk in obtaining security certification to field GPS receivers in unclassified environments. According to officials, however, neither the delay in the preliminary design review nor the risk areas is expected to delay the program's entry into system development, scheduled for November 2014.

Estimated Program Cost and Quantity (fiscal year 2014 dollars):
Total program: TBD
Research and development: $1,658.0 million
Procurement: TBD
Quantity: 124 (development), 550 (production)



Next Major Program Event: Preliminary design review, April 2014

Program Office Comments: In commenting on a draft of this assessment, the Air Force affirmed that it continues to strive to field military-code GPS receivers as quickly as possible. The service has leveraged previous technology and industry experience to mitigate risk and reduce cost, and seeks additional opportunities to streamline the MGUE acquisition. The program office also provided technical comments, which have been incorporated where appropriate.

4179 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Next Generation Jammer (NGJ)

The Navy's Next Generation Jammer (NGJ) is being developed as an external jamming pod system fitted on carrier-based EA-18G Growler aircraft. It will replace the ALQ-99 jamming pod system and provide enhanced airborne electronic attack capabilities to disrupt and degrade enemy air defense and ground communication systems. The Navy plans to field capabilities in three increments for different radio frequency ranges beginning with Increment 1 (mid-band) in 2020 with Increments 2 and 3 (low- and high-band) to follow. We assessed Increment 1.

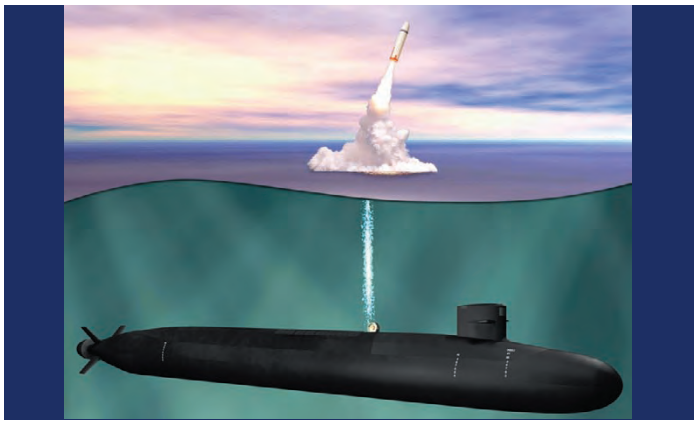
Source: U.S. Navy.

Current Status

In July 2013, DOD approved NGJ Increment 1's entry into technology development; however, work was delayed when GAO sustained a protest related to the technology development contract award. Prior to technology development, the Navy completed a 33-month technology maturation phase, during which the Navy selected four contractors to prototype key technologies and subsystems related to their proposed NGJ Increment 1 concept. According to program officials, each contractor chose the technologies to prototype during technology maturation, but they generally aligned with five critical technology areas—power generation and distribution, exciters, beam formers, amplifiers, and apertures. DOD believes that these prototyping activities meet the competitive prototyping requirements of the Weapon Systems Acquisition Reform Act of 2009, which require competitive prototyping for MDAPs before system development unless a waiver is granted. The program office stated it is also planning to use open systems architecture to enhance future competitions and to provide flexibility for upgrades.

Following technology maturation, the Navy awarded a single $280 million contract to Raytheon for technology development with plans to award a sole-source follow-on contract to complete system development for Increment 1. In October 2011, the Navy stated that it expected to save about $641 million by using only one contractor for technology development. In November 2013, GAO sustained portions of BAE Systems' protest of the contract award and recommended that the Navy document a reevaluation of the proposals and a cost/technical tradeoff analysis. In January 2014, the Navy reaffirmed Raytheon's contract award and resumed NGJ's technology development efforts after a 6-month delay, but faces a $100 million funding reduction.

Estimated Program Cost and Quantity (fiscal year 2014 dollars):
Total program: $6,336.3 million
Research and development: $2,894.6 million
Procurement: $3,442.7 million
Quantity: 9 (development), 114 (procurement)



Next Major Program Event: System development start, second quarter fiscal year 2016

Program Office Comments: The NGJ program office provided technical comments, which were incorporated as appropriate. The Navy is reviewing its schedule to identify actions to maintain its fiscal year 2020 fielding date for NGJ Increment 1.

4180 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Ohio-Class Replacement (OR)

The Navy's *Ohio*-class Replacement (OR) will replace the current fleet of *Ohio*-class ballistic missile submarines (SSBNs) as they begin to retire in 2027. The Navy began technology development in January 2011 in order to avoid a gap in sea based nuclear deterrence between the *Ohio*-class's retirement and the production of a replacement. The Navy is working with the United Kingdom to develop a common missile compartment for use on OR and the United Kingdom's replacement SSBN. OR will initially carry the Trident II D5LE missile.

Source: © 2012 General Dynamics Electric Boat.

Current Status

Navy officials stated that they are pursuing design for affordability initiatives and investigating various contracting and acquisition scenarios to reduce average follow-on ship procurement costs from an estimated $5.6 to $4.9 billion (in fiscal year 2010 dollars).The program intends to maximize economic order quantity benefits by leveraging the *Virginia*-class program and the elements common with the United Kingdom's SSBN. Program officials stated the OR and *Virginia*-class programs are aligned to support various contracting scenarios, including procuring the lead OR concurrently in a multi-year procurement with the Block V *Virginia*-class contract. The Navy would develop a legislative proposal in 2017 to support this approach. The lead ship would likely not meet multi-year procurement criteria that require a stable design that has typically completed initial operational test and evaluation. The Navy has set initial configurations for areas including the torpedo room, bow, and stern. In 2014, the program expects to complete initial specifications, set ship length—a major milestone—and start detailed system descriptions and arrangements. The contractor plans to build a notional submarine section to validate the fidelity of its new design tool. The program plans to have 83 percent of design disclosures (including drawings, and material procurement and construction planning information) and 100 percent of arrangements and the three-dimensional product model completed prior to the start of lead ship construction scheduled for fiscal year 2021. Program officials stated that unmitigated, a sequestration of 2014 funds would result in up to a one year delay to the program (potentially creating a gap in sea-based nuclear deterrence), but that they will attempt to mitigate any delays to the fullest extent allowed.

Estimated Program Cost and Quantity (fiscal year 2014 dollars):
Total program: $95,103.2 million
Research and development: $11,718.2 million
Procurement: $83,385.0 million
Quantity: 12

Next Major Program Event: System requirements review, fiscal year 2014

Program Office Comments: According to the program office, the OR program multi-year-procurement decision has not been made at this time. The OR program intends to maximize savings from cross-class contracting with the *Virginia*-class and the United Kingdom's *Successor*-class to take advantage of benefits from economic order quantity. The OR program is currently conducting analysis on multi-year-procurement and other contracting scenarios.

4181 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Presidential Aircraft Recapitalization (PAR)

The Air Force's Presidential Aircraft Recapitalization (PAR) program is intended to recapitalize the VC-25A system and support the United States President as Head of State, Chief Executive, and Commander in Chief. PAR's principal mission is to provide the President and his staff air transportation with the same level of security and communications capability available at the White House.

Source: U.S. Air Force.

Current Status

PAR program acquisition strategy development is ongoing with milestone decision authority approval expected in the fourth quarter of fiscal year 2015. According to program officials, the program intends to acquire a large, commercial-derivative aircraft and modify it to meet desired capabilities. The program intends to seek a waiver from the requirement to conduct competitive prototyping prior to entry into engineering and manufacturing development. To ensure some form of competition, the program plans to use open architecture for future upgrades.

Since fiscal year 2012, the PAR program has conducted initial planning activities including assessing risk and systems engineering as well as analysis related to requirements, sustainment, and technology and manufacturing maturity. Risk reduction studies are planned to continue through fiscal year 2014.

The PAR system development start and contract award are expected in the fourth quarter of fiscal year 2015. Program officials reported that at present, the Air Force is still determining the number of aircraft needed to replace the current VC-25A fleet and no decision has been made on PAR fleet size. The first aircraft will be used to support research, development, test, and evaluation. Once the development is completed, the aircraft will be delivered as a fully capable aircraft to support presidential missions in fiscal year 2023. Additional deliveries will commence starting in fiscal year 2025. According to program officials, requirements are being finalized with Air Mobility Command but at the time of our review, critical technologies have not yet been identified. Officials reported that program affordability is under discussion, but no targets for the final program cost have been determined yet.

Estimated Program Cost and Quantity (fiscal year 2014 dollars):
Total program: TBD
Research and development (fiscal years 2010 through 2018): $1,075.9 million
Procurement: TBD
Quantity: TBD

Next Major Program Event: Milestone decision authority approval of acquisition strategy, fourth quarter fiscal year 2015.

Program Office Comments: Technical comments were incorporated as appropriate.

4182 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Space Based Infrared Satellite System (SBIRS High)

The Air Force's SBIRS High satellite system is being developed to replace the Defense Support Program and perform a range of missile warning, missile defense, technical intelligence, and battlespace awareness missions. SBIRS High will consist of four satellites in geosynchronous earth orbit (GEO), two sensors on host satellites in highly elliptical orbit (HEO), two replenishment satellites and sensors, and fixed and mobile ground stations. We assessed the space segment and made observations about the ground segment.

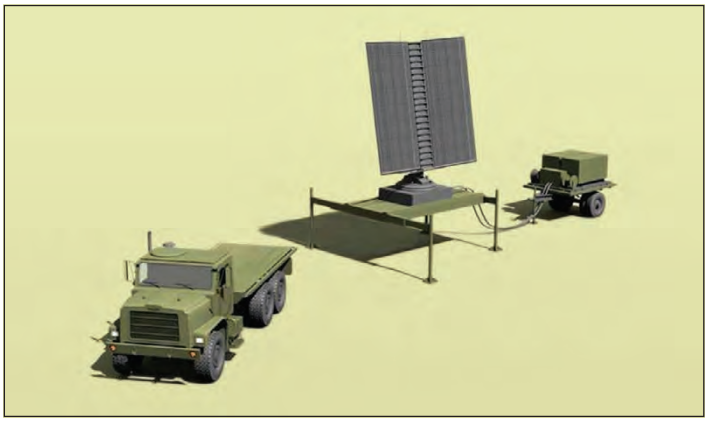
Source: © 2007 Lockheed Martin.

Current Status

Both HEO sensors and the first two GEO satellites have been launched. One of two replenishment sensors was delivered to the host this year for integration, and the third and fourth satellites are currently in production. In October 2013, the first GEO satellite was accepted as operational, with previously identified issues resolved. This means that the data returned from the satellite is reliable. The second satellite was accepted for operations in November 2013. Each GEO satellite carries a scanning sensor and a staring sensor, which provide different data to meet program missions. The program launched the first satellite without event recovery software intended to re-establish ground control of the satellite in the event of an unforeseen failure, so that other software issues could be addressed. Given successful recovery software testing on the second GEO satellite, the Air Force plans to upload the software to the first satellite in the fourth quarter of 2014.

The Block 10 software ground system increment is expected to be delivered in March 2016, and is intended to facilitate processing of integrated data from the Defense Support Program satellites, HEO sensors and GEO satellites now on-orbit. According to the program, this software delivery will also provide the capability for fully-tuned starer sensor data, which means that the data returned from the satellites will be cleared of background noise, such as irrelevant light sources. This capability was previously planned for inclusion in a subsequent Block 20 software delivery which is expected to achieve certification in June 2018. The program plans to fully meet operational requirements in 2019 once it has established the full on-orbit constellation of HEO sensors, four GEO satellites, completion of Blocks 10 and 20, and delivery of its mobile ground assets.

Estimated Program Cost and Quantity (fiscal year 2014 dollars):
Total Program: $18,886.4 million
Research & development: $11,805.5 million
Procurement: $6,817.2 million
Quantity: 6



Next Major Program Event: Third GEO satellite available for delivery December 2015

Program Office Comments: In commenting on a draft of this assessment, program officials noted that the first and second satellites are operationally accepted by US Strategic Command. The third is expected early, but will need to be stored. The ground system, and fourth sensor and satellite are on-track. The fifth and sixth satellite production contract is expected fiscal year 2014.

4183 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Three-Dimensional Expeditionary Long-Range Radar (3DELRR)

The Air Force's 3DELRR is being developed as a long-range, ground-based sensor for detecting, identifying, tracking, and reporting aircraft and missiles for the Joint Forces Air Component Commander. It is intended to provide real-time data and support a range of expeditionary operations in all types of weather and terrain. It is being acquired to replace the Air Force's AN/TPS-75 radar systems.

Source: U.S. Air Force.

Current Status

The 3DELRR program entered technology development in May 2009, and these efforts included capability demonstrations of three competing prototypes. The program is scheduled to enter system development in June 2014 after it completes the source selection process for its development and initial production contract. The acquisition strategy for the program has changed in the last year. The program previously planned to award the system development and low-rate initial production contract using full and open competition. However, when the Air Force released the request for proposals for this contract in November 2013, the program limited the competition to the three contractors that had developed full-scale prototypes and completed a preliminary design review—Lockheed Martin, Northrop Grumman, and Raytheon. According to program officials, including other contractors would require more development funding to reach maturity and these costs would not likely be recouped through full and open competition. However, the program plans to take other steps, such as obtaining data rights, to maintain the ability to introduce competition for subsystems and upgrades later. The maximum total ceiling price for the planned contract is $534 million, which includes an option for low-rate initial production.

The 3DELRR program will enter system development with its critical technologies nearing maturity. The program office reported that 3DELRR successfully demonstrated its eight critical technologies and its manufacturing processes in a relevant environment during its technology development efforts. According to the program office, the greatest risk to program execution is budget uncertainty.

Estimated Total Program Cost and Quantity (fiscal year 2014 dollars):
Total Program: $1,531.4 million
Research and development: $543.4 million
Procurement: $988.1 million
Quantities: 35

Next Major Program Event: System development start, June 2014

Program Office Comments: The program office concurred with this assessment.

4184 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Unmanned Carrier-Launched Airborne Surveillance and Strike (UCLASS) System

The Navy's UCLASS system is expected to address a gap in persistent sea-based intelligence, surveillance, and reconnaissance (ISR) with precision strike capabilities. The system is made up of three key segments an unmanned aerial vehicle, aircraft carrier modifications, and a control system. Working together these segments will provide aircraft carriers with additional ISR as well as targeting and strike capabilities.

Source: U.S. Navy.

Current Status

In June 2013, the Under Secretary of Defense for Acquisition, Technology, and Logistics approved the Navy's plan to invest an estimated $3.7 billion through fiscal year 2020 to develop, produce, and field an initial UCLASS system with up to 24 air vehicles and modify up to four aircraft carriers, to support an early operational capability. The Navy plans to manage UCLASS as a technology development program, and does not plan to hold a formal review to enter system development until after an initial system is fielded in fiscal year 2020. Normally, activities like those planned by the Navy are commensurate with an acquisition program in system development and early production. Using this approach, the Navy is considering seeking approval to bypass a formal system development phase and proceed directly into production in fiscal year 2020 but no formal decision has been made. This approach raises concerns as the Navy could develop, produce, and field a system before undergoing the key oversight mechanisms and reviews that typically govern a program in system development.

In August 2013, the Navy awarded four separate limited source firm fixed-price contracts to develop designs for the air vehicle segment. In fiscal year 2014, the Navy plans to review those preliminary designs, conduct a full and open competition, and award a single contract to complete development and deliver the air vehicles. UCLASS is critically dependent on the development and fielding of the Joint Precision Approach and Landing System (JPALS), a global positioning system that guides aircraft onto an aircraft carrier. Navy officials expect UCLASS to hold a preliminary design review—including the air vehicle, carrier, and control segments—in May 2014 based on JPALS test progress. However, the Navy still considers JPALS one of its top risks for UCLASS.

Estimated Program Cost and Quantity (fiscal year 2014 dollars):
Total program: TBD
Research and development: $3,700 million
Procurement: TBD
Quantity: TBD

Next Major Program Event: Technology development start, 2014

Program Office Comments: According to program officials, the UCLASS program continues to progress toward conducting a milestone A defense acquisition board review in accordance with the program's approved technology development strategy. A milestone B decision will be sought and appropriate documentation submitted for review. The program also provided technical comments, which were incorporated as appropriate.

4185 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Agency Comments and Our Evaluation

DOD provided written comments on a draft of this report. The comments are reprinted in appendix VII. We also received technical comments from DOD, which have been addressed in the report as appropriate.

In its comments, DOD stated that our assessment shows that the Department's commitment to acquisition excellence in the "Better Buying Power" initiatives continues to have a positive impact on the cost, schedule, and performance measures of the programs we assessed. As we note in the report, these initiatives seem to be having a positive effect at least in the near term. This is particularly true for DOD's implementation of "should-cost" reviews which many programs reported were responsible for significant savings. Our assessment also notes that there are still opportunities to find additional savings with two other acquisition reform efforts—affordability constraints and the promotion of competition before and after development start.

Our report also emphasizes that further implementation of knowledge-based best practices are fundamental to containing cost growth and ensuring timely delivery of the capabilities promised to the warfighter in the long term. These include early systems engineering reviews, mature technologies before development start, and the demonstration of mature designs through system-level prototyping.

We are sending copies of this report to appropriate congressional committees; the Secretary of Defense; the Secretaries of the Army, Navy, and Air Force; and the Director of the Office of Management and Budget. In addition, the report will be made available at no charge on the GAO Web site at http://www.gao.gov.

Scope and Methodology

Analysis of the Cost Performance of DOD's Portfolio of Major Defense Acquisition Programs

To develop our observations on the overall changes in the size, cost, and cycle time of Department of Defense's portfolio of major defense acquisition programs, we obtained and analyzed cost, quantity, and schedule data from Selected Acquisition Reports (SAR) and other information in the Defense Acquisition Management Information Retrieval (DAMIR) Purview system, referred to as DAMIR.[1] We converted all cost information to fiscal year 2014 dollars using conversion factors from the DOD Comptroller's National Defense Budget Estimates for Fiscal Year 2014 (table 5-9). Data for the total planned investment of major defense acquisition programs were obtained from DAMIR, which we aggregated for all programs using fiscal year 2014 dollars. Through discussions with DOD officials responsible for the database and confirming selected data with program offices, we determined that the SAR data and the information retrieved from DAMIR were sufficiently reliable for our purposes. In general, we refer to the 80 major defense acquisition programs with SARs dated December 2012 as DOD's 2013 or current portfolio and use a similar convention for prior year portfolios. We compared the programs that issued SARs in December 2012 with the list of programs that had issued SARs in December 2011 (2012 portfolio) to identify the programs that exited and entered the current portfolio. The Missile Defense Agency's Ballistic Missile Defense System is excluded from all analyses as the program does not have an integrated long-term baseline which prevents us from assessing the program's cost progress or comparing it to other major defense acquisition programs.

To determine the portfolio trends over the past ten years we collected data from the annual December SARs for the years 2003 (2004 portfolio) through 2012 (2013 portfolio). The 2009 portfolio is excluded because no annual SARs were released for the December 2008 submission date. We then analyzed the data to determine the number of programs in each portfolio year as well as the year-by-year totals for research and development, procurement, and other acquisition funding for each portfolio year as well as the total amount of funding invested or remaining and, in specific cases the amount due to cost growth. We also used DAMIR and SAR data to make a determination of system type for each program to determine the mix of system types in each portfolio year.

[1]DAMIR Purview is an executive information system operated by the Office of the Under Secretary of Defense for Acquisition, Technology, and Logistics/Acquisition Resources and Analysis.

4189 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

To determine the cost and schedule changes on defense acquisition programs in the current portfolio over the past year, 5 years, and from baseline estimates, we collected data from December 2012, December 2011, and December 2007 SARs; acquisition program baselines; and program offices. For programs less than a year old, we calculated the difference between the December 2012 SAR current estimate and the first full estimate to identify the cost and schedule change over the past year. For programs less than 5 years old, we took a similar approach when calculating the cost and schedule change over the past 5 years. We retrieved data on research, development, test, and evaluation; procurement; total acquisition cost, and schedule estimates for the 80 programs in the 2013 portfolio.[2] In some cases, we divided four programs into two distinct elements, because DOD reports performance data on them separately. As a result some of our analysis reflects a total of 84 programs and sub-elements. We analyzed the data to determine the change in research and development, procurement, and total acquisition costs as well as schedule changes from the first full estimate, generally development start, to the current estimate in the December 2012 SAR. For the programs that did not have a development estimate, we compared the current estimate to the production estimate. Also, for the shipbuilding programs that had a planning estimate, we compared the current estimate to the planning estimate. For programs that began as non–major defense acquisition programs, the first full estimate we used as a baseline may be different than the original baseline disclosed in DOD SARs. We obtained schedule information and calculated the cycle time from program start to initial operational capability and the delay in obtaining initial operational capability. For programs in the current portfolio where schedule data for initial operational capability was not available over the past year, 5 years, and since first full estimates we used the same methodology as used when calculating cost change.

To determine whether programs experienced an increase or decreases in buying power over the past year, we obtained data on program acquisition unit cost to determine whether a program's buying power had increased or decreased. We reviewed SARs for those programs with changes in buying power over the past year to measure the extent to which changes in

[2]We refer to research, development, test, and evaluation costs as research and development or simply as development costs in this report. Total acquisition cost includes research and development and procurement costs as well as acquisition related operation and maintenance and system-specific military construction costs.

4190 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

quantity impacted procurement cost changes. When analyzing buying power changes, we also calculated the amount of procurement cost growth attributable to quantity changes, we isolated the change in procurement quantities and the prior-year's acquisition procurement unit cost for programs over the past year. For those programs with a change in procurement quantities, we calculated the amount attributable to quantity changes as the change in quantity multiplied by the average procurement unit cost for the program a year ago. The resulting dollar amount is considered a change due solely to shifts in the number of units procured and may overestimate the amount of change expected when quantities increase and underestimate the expected change when quantities decrease as it does not account for other effects of quantity changes on procurement such as gain or loss of learning in production that could result in changes to unit cost over time or the use or absence of economic orders of material. However, these changes are accounted for as part of the change in cost not due to quantities.

To evaluate program performance against high-risk criteria discussed by DOD, the Office of Management and Budget (OMB), and GAO, we calculated how many programs had less than a 2 percent increase in total acquisition cost over the past year, less than a 10 percent increase over the past 5 years, and less than a 15 percent increase from first full estimates using data from December 2012, December 2011, and December 2007 SARs; acquisition program baselines; and program offices. For programs that began as non–major defense acquisition programs, the first full estimate we used as a baseline may be different than the original baseline contained in DOD SARs. We also compared the performance of the 2013 portfolio in each high-risk category with the performance of the 2012 and 2011 portfolios we reported on in prior years to identify any positive or negative changes. For programs with multiple sub-programs presented in the SARs we calculated the net effect of the sub-programs to reach an aggregate program result.

To discern the cost and schedule performance of the various system types represented in the current portfolio, we first determined each program's system type using DAMIR reported information on commodity type, the program's mission and description summary from the December 2012 SAR, and GAO analyst judgment. The programs were then grouped by system type and cost and schedule change was determined using the cost and schedule changes calculated for the programs in each system type. Development cost change and change in initial operating capability were then calculated for each group as elsewhere in this objective. For change

4191 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

in procurement unit cost, a weighted average calculation was used based on the total procurement cost for programs in each system type.

To determine the funding already invested and the funding remaining that is needed to complete the 80 programs in the 2013 portfolio we used funding stream data obtained from DAMIR and the December 2012 SARs. We define funding invested as all funding that has been provided to the programs in fiscal years 2013 and earlier, while funding remaining is all the amounts that will be provided in the fiscal year 2014 and later. To show the amount of additional future funding needed due to cost growth from first full estimates to complete programs in the current portfolio, we compared a funding stream for each program that corresponded to its first full estimate at program start against the funding stream for the current estimate in the program's December 2012 SAR.

Analysis of Selected DOD Programs Using Knowledge-Based Criteria

To collect data from current and future major defense acquisition programs—including cost and schedule estimates, technology maturity, and planned implementation of acquisition reforms—we distributed two electronic questionnaires, one questionnaire for the 38 current programs and a slightly different questionnaire for the 18 future programs. Both of the questionnaires were sent by e-mail in an attached Microsoft Word form that respondents could return electronically. We received responses from all of the programs we assessed from August to November 2013. To ensure the reliability of the data collected through our questionnaires, we took a number of steps to reduce measurement error and non-response error. These steps included conducting three pretests for the future major defense acquisition program questionnaire and three pretests for the major defense acquisition program questionnaire prior to distribution to ensure that our questions were clear, unbiased, and consistently interpreted; reviewing responses to identify obvious errors or inconsistencies; conducting follow-up to clarify responses when needed; and verifying the accuracy of a sample of keypunched questionnaires. Our pretests covered each branch of the military to better ensure that the questionnaires could be understood by officials within each branch.

Our analysis of how well programs are adhering to a knowledge-based acquisition approach focuses on 38 major defense acquisition programs that are mostly in development or the early stages of production. To assess the knowledge attained by key decision points (system development start or detailed design contract award for shipbuilding programs, critical design review or fabrication start for shipbuilding

4192 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

programs, and production start), we collected data from program offices about their knowledge at each point. In particular, we focused on the seven programs that crossed these key acquisition points in 2013 and evaluated their adherence to knowledge based practices. We also provide some insight into how much knowledge is obtained at key junctures by other programs we assessed as well. We also included observations on the knowledge that 18 future programs expect to obtain before starting development as well as how much knowledge 14 current programs expect to obtain before reaching their production start. We did not validate the data provided by the program offices, but reviewed the data and performed various checks to determine that they were reliable enough for our purposes. Where we discovered discrepancies, we clarified the data accordingly.

The 56 current and future programs included in our assessment were in various stages of the acquisition cycle, and not all of the programs provided information on knowledge obtained at each point. Programs were not included in our assessments at key decision points if relevant data were not available. For each decision point, we summarized knowledge attainment for the number of programs with data that had reached that knowledge point. Our analysis of knowledge attained at each key point includes factors that we have previously identified as being key to a knowledge-based acquisition approach, including holding early systems engineering reviews, testing an integrated prototype prior to the design review, using a reliability growth curve, planning for manufacturing, and testing a production-representative prototype prior to the making a production decision. Additional information on how we collect these data is found in the product knowledge assessment section of appendix I. See also appendix IV for a list of the practices that are associated with a knowledge-based acquisition approach.

Analysis of Acquisition Initiatives and Program Concurrency

To determine how DOD has begun to implement acquisition reforms, we obtained and analyzed the DOD 5000.02 acquisition instruction in place at the time of our review, the Weapon Systems Acquisition Reform Act of 2009, and the September 14, 2010, Under Secretary of Defense for Acquisition, Technology, and Logistics memorandum on “better buying power” as well as subsequent memorandums clarifying and implementing that guidance, including the “Better Buying Power 2.0” memorandum. In November 2013, DOD released an interim revision of its 5000.02 acquisition instruction with the intention of incorporating the policy changes mandated by the act and “Better Buying Power” memos. As our

4193 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

data was collected prior to the release of this revision we did not use the new instruction as criteria for our assessments. To develop our observations, we analyzed questionnaire data received from the 38 current and 18 future major defense acquisition programs in our assessment to determine the extent to which specific acquisition reform issues have been implemented such as establishing affordability constraints, conducting "should-cost" analyses, using competition throughout the acquisition life cycle, and holding configuration steering boards.

To assess program concurrency we identified the programs—among those we included in our assessment—with production start dates. We used the questionnaire responses from those programs to identify the dates for the start and end of developmental testing, compared those dates to the timing of each program's production decision and determined the number of months, if any, of developmental testing done after production start. We then compared the number of overlapping months to the total number of months of developmental testing for each program and calculated the percentage of developmental testing done concurrent with production.

Individual Assessments of Weapon Programs

In total, this report presents individual assessments of 56 weapon programs. A table listing these programs is found in appendix VIII. Out of these programs, 37 are captured in a two-page format discussing technology, design, and manufacturing knowledge obtained and other program issues. Thirty-four of these 37 two-page assessments are of major defense acquisition programs, most of which are in development or early production and 3 assessments are of programs that were projected to become major defense acquisition programs during or soon after our review. The remaining 19 programs are described in a one-page format that describes their current status. Those one-page assessments include 15 future major defense acquisition programs, 2 major defense acquisition program that are well into production, and 2 major defense acquisition programs that were recently restructured or curtailed. Over the past several years, DOD has revised policies governing weapon system acquisitions and changed the terminology used for major acquisition events. To make DOD's acquisition terminology more consistent across the 56 program assessments, we standardized the terminology for key program events. For most individual programs in our assessment, "development start" refers to the initiation of an acquisition program as well as the start of engineering and manufacturing development. This generally coincides with DOD's milestone B. A few programs in our assessment

4194 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

have a separate “program start” date, which begins a pre–system development phase for program definition and risk-reduction activities. This “program start” date generally coincides with DOD’s former terminology for milestone I or DOD’s current milestone A. The “production decision” generally refers to the decision to enter the production and deployment phase, typically with low-rate initial production. The “initial capability” refers to the initial operational capability—sometimes called first unit equipped or required asset availability. For shipbuilding programs, the schedule of key program events in relation to acquisition milestones varies for each program. Our work on shipbuilding best practices has identified the detailed design contract award and the start of lead ship fabrication as the points in the acquisition process roughly equivalent to development start and design review for other programs.

For each program we assessed in a two-page format, we present cost, schedule, and quantity data at the program’s first full estimate and an estimate from the latest SAR or the program office reflecting 2013 data where they were available. The first full estimate is generally the cost estimate established at milestone B—development start; however, for a few programs that did not have such an estimate, we used the estimate at milestone C—production start—instead. For shipbuilding programs, we used their planning estimates if those estimates were available. For systems for which a first full estimate was not available, we only present the latest available estimate of cost and quantities. For the other programs assessed in a one-page format, we present the latest available estimate of cost and quantity from the program office.

For each program we assessed, all cost information is presented in fiscal year 2014 dollars. We converted cost information to fiscal year 2014 dollars using conversion factors from the DOD Comptroller’s National Defense Budget Estimates for Fiscal Year 2014 (table 5-9). We have depicted only the program’s main elements of acquisition cost—research and development and procurement. However, the total program cost also includes military construction and acquisition-related operation and maintenance costs. Because of rounding and these additional costs, in some situations, total cost may not match the exact sum of the research and development and procurement costs. The program unit costs are calculated by dividing the total program cost by the total quantities planned. In some instances, the data were not applicable, and we annotate this by using the term “not applicable (NA).” The quantities listed refer to total quantities, including both procurement and development quantities.

4195 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The schedule assessment for each program is based on acquisition cycle time, defined as the number of months between program start and the achievement of initial operational capability or an equivalent fielding date. In some instances the data were not yet available, and we annotate this by using the term “to be determined (TBD)” or “NA.”

The information presented on the “funding needed to complete” is from fiscal year 2014 through completion and, unless otherwise noted, draws on information from SARs or on data from the program office. In some instances, the data were not available, and we annotate this by the term “TBD” or “NA.” The quantities listed refer only to procurement quantities. Satellite programs, in particular, produce a large percentage of their total operational units as development quantities, which are not included in the quantity figure.

The intent of these comparisons is to provide an aggregate, or overall, picture of a program’s history. These assessments represent the sum of the federal government’s actions on a program, not just those of the program manager and the contractor. DOD does a number of detailed analyses of changes that attempt to link specific changes with triggering events or causes. Our analysis does not attempt to make such detailed distinctions.

In this year’s assessment we also reviewed whether individual subcontracting reports from a program’s prime contractor or contractors were accepted on the Electronic Subcontracting Reporting System (eSRS). We reviewed this information for 36 of the major defense acquisition programs included in our assessment using the contract information reported in their December 2012 Selected Acquisition Reports. See appendix VI for a list of the programs we reviewed. The contract numbers for each program’s prime contracts were entered into the eSRS database to determine whether the individual subcontracting reports had been accepted by the government. While we did not assess the reliability of the eSRS database, we took steps to ensure that the data provided by the database was sufficiently reliable for the purpose of our analysis by interviewing defense officials with knowledge of DOD’s process for eSRS and collecting data from program offices on contract reporting. The government uses individual subcontracting reports on eSRS as one method of monitoring small business participation, as the report includes goals for small business subcontracting. Not all prime contracts for major defense acquisition programs are required to submit individual subcontracting reports. For example, some contractors report small

4196 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

business participation at a corporate level as opposed to a program level and this data is not captured in the individual subcontracting reports.

Product Knowledge Data on Individual Two-Page Assessments

In our past work examining weapon acquisition issues and best practices for product development, we have found that leading commercial firms pursue an acquisition approach that is anchored in knowledge, whereby high levels of product knowledge are demonstrated by critical points in the acquisition process. On the basis of this work, we have identified three key knowledge points during the acquisition cycle—system development start, critical design review, and production start—at which programs need to demonstrate critical levels of knowledge to proceed. To assess the product development knowledge of each program at these key points, we reviewed data-collection instruments and questionnaires submitted by programs; however, not every program had responses to each element of the data-collection instrument or questionnaire. We also reviewed pertinent program documentation and discussed the information presented on the data-collection instrument and questionnaire with program officials as necessary.

To assess a program's readiness to enter system development, we collected data through the data-collection instrument on critical technologies and early design reviews. To assess technology maturity, we asked program officials to apply a tool, referred to as technology readiness levels (TRL), for our analysis. The National Aeronautics and Space Administration originally developed TRLs, and the Army and Air Force science and technology research organizations use them to determine when technologies are ready to be handed off from science and technology managers to product developers. TRLs are measured on a scale from 1 to 9, beginning with paper studies of a technology's feasibility and culminating with a technology fully integrated into a completed product. See appendix V for TRL definitions. Our best-practices work has shown that a TRL 7—demonstration of a technology in a realistic environment—is the level of technology maturity that constitutes a low risk for starting a product development program.[3] For shipbuilding programs, we have recommended that this level of maturity be achieved by the

[3]GAO, *Best Practices: Better Management of Technology Development Can Improve Weapon System Outcomes*, GAO/NSIAD-99-162 (Washington, D.C.: July 30, 1999); and *Best Practices: Better Matching of Needs and Resources Will Lead to Better Weapon System Outcomes*, GAO-01-288 (Washington, D.C.: Mar. 8, 2001).

4197 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

contract award for detailed design.[4] In our assessment, the technologies that have reached TRL 7, a prototype demonstrated in a realistic environment, are referred to as mature or fully mature. Those technologies that have reached TRL 6, a prototype demonstrated in a relevant environment, are referred to as approaching or nearing maturity. Satellite technologies that have achieved TRL 6 are assessed as fully mature due to the difficulty of demonstrating maturity in a realistic environment—space. In addition, we asked program officials to provide the date of the preliminary design review. We compared this date to the system development start date.

In most cases, we did not validate the program offices' selection of critical technologies or the determination of the demonstrated level of maturity. We sought to clarify the TRLs in those cases where information existed that raised concerns. If we were to conduct a detailed review, we might adjust the critical technologies assessed, their readiness levels demonstrated, or both. It was not always possible to reconstruct the technological maturity of a weapon system at key decision points after the passage of many years. Where practicable, we compared technology assessments provided by the program office to assessments conducted by officials from the Office of the Assistant Secretary of Defense for Research and Engineering.

To assess design stability, we asked program officials to provide the percentage of design drawings completed or projected for completion by the design review, the production decision, and as of our current assessment in the data-collection instrument. In most cases, we did not verify or validate the percentage of engineering drawings provided by the program office. We clarified the percentage of drawings completed in those cases where information that raised concerns existed. Completed drawings were defined as the number of drawings released or deemed releasable to manufacturing that can be considered the "build to" drawings. For shipbuilding programs, we asked program officials to provide the percentage of the three-dimensional product model that had been completed by the start of lead ship fabrication, and as of our current assessment. To gain greater insights into design stability, we also asked program officials to provide the date they planned to first integrate and test all key subsystems and components into a system-level integrated prototype. We compared this date to the date of the design review. We did

[4]GAO, *Best Practices: High Levels of Knowledge at Key Points Differentiate Commercial Shipbuilding from Navy Shipbuilding*, GAO-09-322 (Washington, D.C.: May 13, 2009).

4198 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

not assess whether shipbuilding programs had completed integrated prototypes.

To assess production maturity, we asked program officials to identify the number of critical manufacturing processes and, where available, to quantify the extent of statistical control achieved for those processes as a part of our data-collection instrument. In most cases, we did not verify or validate the information provided by the program office. We clarified the number of critical manufacturing processes and the percentage of statistical process control where information existed that raised concerns. We used a standard called the process capability index, a process-performance measurement that quantifies how closely a process is running to its specification limits. The index can be translated into an expected product defect rate, and we have found it to be a best practice. We also used data provided by the program offices on their manufacturing readiness levels (MRL) for process capability and control, a sub-thread tracked as part of the manufacturing readiness assessment process recommended by DOD, to determine production maturity. We assessed programs as having mature manufacturing processes if they reported an MRL 9 for that sub-thread—meaning, that manufacturing processes are stable, adequately controlled, and capable. To gain further insights into production maturity, we asked program officials whether the program planned to demonstrate critical manufacturing processes on a pilot production line before beginning low-rate production. We also asked programs on what date they planned to begin system-level developmental testing of a fully configured, production- representative prototype in its intended environment. We compared this date to the production start date. We did not assess production maturity for shipbuilding programs.

Although the knowledge points provide excellent indicators of potential risks, by themselves they do not cover all elements of risk that a program encounters during development, such as funding instability. Our detailed reviews on individual systems normally provide a more comprehensive assessment of risk elements.

We conducted this performance audit from June 2013 to March 2014, in accordance with generally accepted government auditing standards. Those standards require that we plan and perform the audit to obtain sufficient, appropriate evidence to provide a reasonable basis for our findings and conclusions based on our audit objectives. We believe that the evidence obtained provides a reasonable basis for our findings and conclusions based on our audit objectives.

Current and First Full Estimates for DOD's 2013 Portfolio of Major Defense Acquisition Programs

Table 8 contains the current and first full total acquisition cost estimates (in fiscal year 2013 dollars) for each program or element in the Department of Defense's (DOD) 2013 major defense acquisition program portfolio. For each program we show the percent change in total acquisition cost from the first full estimate, as well as over the past year and 5 years.

Table 8: Current Cost Estimates and First Full Estimates for DOD's 2013 Portfolio of Major Defense Acquisition Programs

Fiscal year 2014 dollars in millions

Program name	Current total acquisition cost	First full estimate total acquisition cost	Change in total acquisition cost from first full estimate (percent)	Change in total acquisition cost within the past year (percent)	Change in total acquisition cost within the past 5 years (percent)
Advanced Extremely High Frequency Satellite (AEHF)	$14,559	$6,700	117.3%	-0.9%	70.2%
AGM-88E Advanced Anti-Radiation Guided Missile (AGM-88E AARGM)	2,062	1,684	22.5	-0.4	15.1
AH-64E Apache New Build (AH-64E New Build)	2,119	2,492	-15.0	2.9	-15.0
AH-64E Apache Remanufacture (AH-64E Remanufacture)	12,499	7,617	64.1	12.9	50.2
AIM-120 Advanced Medium Range Air-to-Air Missile (AMRAAM)	24,052	11,497	109.2	-0.9	23.3
AIM-9X Block II Air-to-Air Missile (AIM-9X Block II)	3,793	4,202	-9.7	-7.0	-9.7
Airborne and Maritime/Fixed Station Joint Tactical Radio System (AMF JTRS)	3,583	8,576	-58.2	-12.9	-58.2
Airborne Warning and Control System Block 40/45 Upgrade (AWACS Blk 40/45 Upgrade)	2,865	2,936	-2.4	-2.4	-2.4
B-2 Extremely High Frequency SATCOM and Computer Increment 1 (B-2 EHF Inc1)	594	747	-20.5	-2.5	-17.5
B61 Mod 12 Life Extension Program Tailkit Assembly (B61 Mod 12 LEP TKA)	1,369	1,375	-0.5	-0.5	-0.5
C-130J Hercules Transport Aircraft (C-130J)	16,455	998	1548.6	-1.9	22.9
C-5 Reliability Enhancement and Re-engining Program (C-5 RERP)	7,661	11,469	-33.2	-1.1	-30.7
CH-47F Improved Cargo Helicopter (CH-47F)	15,000	3,386	343.0	0.3	8.7
CH-53K Heavy Lift Replacement Helicopter (CH-53K)	24,806	17,414	42.5	4.7	42.0
Chemical Demilitarization-Assembled Chemical Weapons Alternatives (Chem Demil-ACWA)	10,496	2,779	277.7	-0.7	34.5
Cooperative Engagement Capability (CEC)	5,491	3,096	77.4	-1.5	2.8
Gerald R. Ford Class Nuclear Aircraft Carrier (CVN 78)	36,008	37,415	-3.8	-0.8	10.5
DDG 1000 *Zumwalt* Class Destroyer (DDG 1000)	22,000	36,602	-39.9	0.2	-26.8
DDG 51 *Arleigh Burke* Class Guided Missile Destroyer (DDG 51)	107,831	15,974	575.0	2.3	30.5

Knowledge-Based Acquisition Practices

GAO's prior work on best product-development practices found that successful programs take steps to gather knowledge that confirms that their technologies are mature, their designs stable, and their production processes are in control. Successful product developers ensure a high level of knowledge is achieved at key junctures in development. We characterize these junctures as knowledge points. The Related GAO Products section of this report includes references to the body of work that helped us identify these practices and apply them as criteria in weapon system reviews. The following table summarizes these knowledge points and associated key practices.

Table 10: Best Practices for Knowledge-based Acquisitions

Knowledge Point 1: Technologies, time, funding, and other resources match customer needs. Decision to invest in product development
Demonstrate technologies to a high readiness level—Technology Readiness Level 7—to ensure technologies will work in an operational environment[a]
Ensure that requirements for product increment are informed by preliminary design review using systems engineering process (such as prototyping of preliminary design)
Establish cost and schedule estimates for product on the basis of knowledge from preliminary design using systems engineering tools (such as prototyping of preliminary design)
Constrain development phase (5 to 6 years or less) for incremental development
Ensure development phase fully funded (programmed in anticipation of milestone)
Align program manager tenure to complete development phase
Contract strategy that separates system integration and system demonstration activities
Conduct independent cost estimate
Conduct independent program assessment
Conduct major milestone decision review for development start
Knowledge Point 2: Design is stable and performs as expected. Decision to start building and testing production-representative prototypes
Complete system critical design review
Complete 90 percent of engineering design drawing packages
Complete subsystem and system design reviews
Demonstrate with system-level integrated prototype that design meets requirements
Complete the failure modes and effects analysis
Identify key system characteristics
Identify critical manufacturing processes
Establish reliability targets and growth plan on the basis of demonstrated reliability rates of components and subsystems

4205 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

(Continued From Previous Page)
Conduct independent cost estimate
Conduct independent program assessment
Conduct major milestone decision review to enter system demonstration
Knowledge Point 3: Production meets cost, schedule, and quality targets. Decision to produce first units for customer
Demonstrate manufacturing processes
Build and test production-representative prototypes to demonstrate product in intended environment
Test production-representative prototypes to achieve reliability goal
Collect statistical process control data
Demonstrate that critical processes are capable and in statistical control
Conduct independent cost estimate
Conduct independent program assessment
Conduct major milestone decision review to begin production

Source: GAO.

Note: DOD considers Technology Readiness Level 6, demonstrations in a relevant environment, to be appropriate for programs entering system development; therefore we have analyzed programs against this measure as well.

4206 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Technology Readiness Levels

Technology readiness level		Description	Hardware/software	Demonstration environment
1.	Basic principles observed and reported	Lowest level of technology readiness. Scientific research begins to be translated into applied research and development. Examples might include paper studies of a technology's basic properties	None (paper studies and analysis)	None
2.	Technology concept and/or application formulated	Invention begins. Once basic principles are observed, practical applications can be invented. The application is speculative and there is no proof or detailed analysis to support the assumption. Examples are still limited to paper studies.	None (paper studies and analysis)	None
3.	Analytical and experimental critical function and/or characteristic proof of concept	Active research and development is initiated. This includes analytical studies and laboratory studies to physically validate analytical predictions of separate elements of the technology. Examples include components that are not yet integrated or representative.	Analytical studies and demonstration of nonscale individual components (pieces of subsystem)	Lab
4.	Component and/or breadboard validation in laboratory environment	Basic technological components are integrated to establish that the pieces will work together. This is relatively "low fidelity" compared to the eventual system. Examples include integration of "ad hoc" hardware in a laboratory.	Low-fidelity breadboard. Integration of nonscale components to show pieces will work together. Not fully functional or form or fit but representative of technically feasible approach suitable for flight articles.	Lab
5.	Component and/or breadboard validation in relevant environment	Fidelity of breadboard technology increases significantly. The basic technological components are integrated with reasonably realistic supporting elements so that the technology can be tested in a simulated environment. Examples include "high fidelity" laboratory integration of components.	High-fidelity breadboard. Functionally equivalent but not necessarily form and/or fit (size weight, materials, etc). Should be approaching appropriate scale. May include integration of several components with reasonably realistic support elements/subsystems to demonstrate functionality.	Lab demonstrating functionality but not form and fit. May include flight demonstrating breadboard in surrogate aircraft. Technology ready for detailed design studies.

4207 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

(Continued From Previous Page)

Technology readiness level		Description	Hardware/software	Demonstration environment
6.	System/subsystem model or prototype demonstration in a relevant environment	Representative model or prototype system, which is well beyond the breadboard tested for TRL 5, is tested in a relevant environment. Represents a major step up in a technology's demonstrated readiness. Examples include testing a prototype in a high fidelity laboratory environment or in simulated realistic environment.	Prototype. Should be very close to form, fit and function. Probably includes the integration of many new components and realistic supporting elements/subsystems if needed to demonstrate full functionality of the subsystem.	High-fidelity lab demonstration or limited/restricted flight demonstration for a relevant environment. Integration of technology is well defined.
7.	System prototype demonstration in a realistic environment	Prototype near or at planned operational system. Represents a major step up from TRL 6, requiring the demonstration of an actual system prototype in a realistic environment, such as in an aircraft, vehicle or space. Examples include testing the prototype in a test bed aircraft.	Prototype. Should be form, fit and function integrated with other key supporting elements/subsystems to demonstrate full functionality of subsystem.	Flight demonstration in representative realistic environment such as flying test bed or demonstrator aircraft. Technology is well substantiated with test data.
8.	Actual system completed and "flight qualified" through test and demonstration	Technology has been proven to work in its final form and under expected conditions. In almost all cases, this TRL represents the end of true system development. Examples include developmental test and evaluation of the system in its intended weapon system to determine if it meets design specifications.	Flight-qualified hardware	Developmental Test and Evaluation (DT&E) in the actual system application.
9.	Actual system "flight proven" through successful mission operations	Actual application of the technology in its final form and under mission conditions, such as those encountered in operational test and evaluation. In almost all cases, this is the end of the last "bug fixing" aspects of true system development. Examples include using the system under operational mission conditions.	Actual system in final form	Operational Test and Evaluation (OT&E) in operational mission conditions.

Major Defense Acquisition Programs' Individual Subcontracting Reports in the Electronic Subcontracting Reporting System

Table 11 contains the numbers of individual subcontracting reports from the prime contractor for the programs we assessed that were accepted on the Electronic Subcontracting Reporting System (eSRS). We reviewed this information for the 36 major defense acquisition programs included in our individual program assessments using the prime contracts reported in available Selected Acquisition Reports. The government uses individual subcontracting reports on eSRS as one method of monitoring small business participation, as the report includes goals for small business subcontracting. There are multiple reasons why a program may not have an accepted subcontracting report in eSRS. For example, some programs may have pending or rejected reports within the system as all reports are reviewed prior to acceptance. Not all prime contracts for major defense acquisition programs are required to submit individual subcontracting reports. Instead, some contractors report small business participation at a corporate level as opposed to the program level and this data is not captured in the individual subcontracting reports.[1] Specifically, the F-35 program provided questionnaire data indicating that for the five contracts listed in the December 2012 SAR all report at the comprehensive, contractor level. Similarly for the three contracts listed by JLTV program officials, questionnaire data shows that one of them reports on small business participation at the corporate level with no participation information specific to the JLTV program. Finally, although a program may be required to submit a report it may not yet have done so for the period we reviewed.

[1]Twelve large defense contractors are participants under the Test Program for Negotiation of Comprehensive Small Business Subcontracting Plans created by the National Defense Authorization Act for Fiscal Years 1990 and 1991, Pub. L. No. 101-189, § 834 (1989) and have each established a comprehensive subcontracting plan on a corporate, division or plant-wide basis under which a single summary subcontract report is submitted semi-annually for all covered DOD contracts. The test program has been extended by Congress several times with the current three year extension made by Pub. L. No. 112-81, § 866 (2011) to end on December 31, 2014. Participation in the test program is on a voluntary basis such that the 12 participants may have contracts where they are reporting on an individual basis as well as contracts where they are reporting on a comprehensive basis.

Comments from the Department of Defense

OFFICE OF THE UNDER SECRETARY OF DEFENSE
3000 DEFENSE PENTAGON
WASHINGTON, DC 20301-3000

ACQUISITION, TECHNOLOGY AND LOGISTICS

21 MAR 2014

Mr. Michael J. Sullivan
Director, Acquisition and Sourcing Management
U.S. Government Accountability Office
441 G St NW
Washington, DC 20548

Dear Mr. Sullivan,

This is the Department of Defense response to the GAO Draft Report, GAO-14-340SP, "Defense Acquisitions: Assessments of Selected Weapon Programs" dated March 2014 (GAO Code 121144).

The Department is pleased that this year's Draft Report, the 12th annual assessment on the performance of DoD's major acquisition programs, is the most encouraging to date. GAO results indicate that the Department's commitment to acquisition excellence in the Better Buying Power initiatives continue to have a positive impact on cost, schedule, and performance measures of our programs.

The Under Secretary of Defense for Acquisition, Technology, and Logistics will again publish a comprehensive report on the acquisition system in 2014. The 2nd annual report will be a data driven analysis that provides transparent and objective performance measures of our major acquisition programs and contracts. The fiscal environment remains challenging and continues to put downward pressure on investment funding. Continued improvement of the acquisition system will require a more clear understanding of how decisions throughout the process influence performance.

The Department appreciates the opportunity to comment on the Draft Report. My point of contact for this effort is Mr. Joe Beauregard, 703-697-8046.

Sincerely,

Nancy L. Spruill

GAO's Mission

The Government Accountability Office, the audit, evaluation, and investigative arm of Congress, exists to support Congress in meeting its constitutional responsibilities and to help improve the performance and accountability of the federal government for the American people. GAO examines the use of public funds; evaluates federal programs and policies; and provides analyses, recommendations, and other assistance to help Congress make informed oversight, policy, and funding decisions. GAO's commitment to good government is reflected in its core values of accountability, integrity, and reliability.

Obtaining Copies of GAO Reports and Testimony

The fastest and easiest way to obtain copies of GAO documents at no cost is through GAO's Web site (www.gao.gov). Each weekday afternoon, GAO posts on its Web site newly released reports, testimony, and correspondence. To have GAO e mail you a list of newly posted products, go to www.gao.gov and select "E-mail Updates."

Order by Phone

The price of each GAO publication reflects GAO's actual cost of production and distribution and depends on the number of pages in the publication and whether the publication is printed in color or black and white. Defense Acquisitions: Military Services Consistently Held Required Configuration Steering Boards That Actively Reviewed Requirements Changes

The Department of Defense (DOD) established Configuration Steering Boards (CSBs) in 2007 as a measure to control requirements changes and associated cost increases on its major defense acquisition programs (MDAPs).[1] These boards are a forum for senior acquisition, funding, and requirement leaders in the Office of the Secretary of Defense, Joint Staff, and the military services to review proposed changes to program requirements or system configurations that have the potential to adversely affect program cost or schedule.[2] Congress has also identified CSBs as a way to control requirements. In the Duncan Hunter National Defense Authorization Act for Fiscal Year 2009, Congress directed DOD to establish and hold annual CSBs for the military services' MDAPs.[3]

In July 2011, we found that the military services held a CSB review for about 77 percent of the MDAPs in 2010, and that programs varied in how they used the boards to control requirements and mitigate cost and schedule risks. [4] In addition, we found that not all of the required officials were invited to participate in the board meetings, particularly in the Navy. We recommended that the Navy amend its policy to ensure that all statutorily required participants are included, and that DOD amend its CSB policy to be consistent with statute and align CSBs with other reviews when possible. Since then, the Navy has updated its guidance to explicitly include the Joint Staff

[1] MDAPs are those estimated by DOD to require an eventual total expenditure for research, development, test, and evaluation of more than $480 million, or for procurement of more than $2.79 billion, in fiscal year 2014 constant dollars.

[2] A requirement is an established need justifying the timely allocation of resources to achieve a capability to accomplish approved military objectives, missions, or tasks. These are often communicated in requirements and other documentation as key performance parameters, key system attributes, or contract specifications. Configuration refers to the functional and physical characteristics of a product.

[3] Pub L. No 110-417, §814 (2008). The Under Secretary of Defense for Acquisition, Technology and Logistics recently directed the military services to employ the Configuration Steering Board construct for all acquisition category levels.

and the Office of the Secretary of Defense as CSB participants. In November 2013, DOD amended its CSB policy to ensure that statutorily required participants are included and require annual CSBs for programs in production and sustainment, among other things.[5]

The Senate Report accompanying the National Defense Authorization Act for Fiscal Year 2014 mandated GAO to review DOD's implementation of the CSB process.[6] This report examines the extent to which (1) the military services have held CSBs, and (2) CSBs were approving requirements changes that could impact cost and schedule outcomes.

To conduct this work, we reviewed the Duncan Hunter National Defense Authorization Act for Fiscal Year 2009 and acquisition guidance related to CSBs. Using the Defense Acquisition Management Information Retrieval System, we identified 79 current MDAPs that are required to hold annual CSBs.[7] For each program, we asked the acquisition organization overseeing it—the Air Force, Army, or Navy—to provide the minutes, briefing slides, or other documentation related to the meetings. Specifically, we examined 2013 CSB documentation to determine when the meetings were held; whether requirements and technical configuration increases or decreases were proposed; and if the boards approved the changes. For 12 Navy programs that conducted a CSB in 2013, we were unable to determine if requirements and technical configuration changes were proposed to and approved by the CSB, because the Navy was unable to provide appropriate documentation for these programs. Therefore, we excluded the following programs when determining whether CSBs were approving requirements changes that could impact cost and schedule outcomes: CH-53K Heavy Lift Replacement Helicopter, EA-18G Growler Aircraft, Ground/Air Task Oriented Radar, H-1 Upgrades, Joint Standoff Weapon-Baseline Variant and Unitary Warhead Variant, KC-130J Transport Aircraft, MH-60R Multi-Mission Helicopter, MH-60S Fleet Combat Support Helicopter, Mobile User Objective System, Tactical Tomahawk RGM-109E/UGM-109E Missile, V-22 Osprey Joint Service Advanced Vertical Lift Aircraft, and MQ-8 Vertical Takeoff and Landing Tactical Unmanned Aerial Vehicle Fire Scout.

We also interviewed officials from the Joint Staff, and acquisition and requirements organizations regarding the services' use of CSBs. Finally, we used information gathered from our latest annual weapon acquisition assessment to determine if programs were changing requirements without the approval of a CSB.[8] Our annual weapon acquisition assessment includes a non-generalizable sample of Air Force, Army, and Navy weapon programs in both development and production phases. We assessed program responses to a standard set of questions and identified programs that reported requirements changes in fiscal year 2013. We interviewed program officials to determine whether these requirements changes were presented to the CSB for review.

[5] DOD's Interim Department of Defense Instruction 5000.02, Operation of the Defense Acquisition System (Nov. 25, 2013) contains other modifications to defense acquisition policy which were not relevant for our review.

[6] S. Rep. No. 113-44, at 144 (2013).

[7] We defined current MDAPs as those included in DOD's Defense Acquisition Management Information Retrieval system's official MDAP list. We excluded two programs, the Ballistic Missile Defense System and Chemical Demilitarization-Assembled Chemical Weapons Alternatives, from our analysis because statutory requirements for Configuration Steering Boards only apply to military department major defense acquisition programs. These programs are managed by the Missile Defense Agency and the Assistant Secretary of Defense for Nuclear, Chemical, and Biological Defense programs, respectively.

4222 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

We conducted this performance audit from February 2014 to May 2014 in accordance with generally accepted government auditing standards. Those standards require that we plan and perform the audit to obtain sufficient, appropriate evidence to provide a reasonable basis for our findings and conclusions based on our audit objectives. We believe that the evidence obtained provides a reasonable basis for our findings and conclusions based on our audit objectives.

Results in Brief

In 2013, the military services held a Configuration Steering Board (CSB) for 77 of 79 current MDAPs required to hold one by statute, approximately 97 percent. The Army and Air Force held meetings for all of their programs, while the Navy did not hold a CSB for two of its programs because one program began development in 2013 and the other program had its board cancelled and rescheduled in 2014 in an effort to reduce costs. We also found that the services combined these boards for similar programs or held them in combination with other reviews, although the Navy held some CSB meetings without officials from the Joint Staff and the Office of the Secretary of Defense in attendance.

Based on information the military services were able to provide on 65 of the 77 programs that held a CSB in 2013, the boards actively reviewed and approved requirements or technical configuration changes proposed by eight programs. The boards approved decreases or deferrals for four of the programs, increases for two programs, and both increases and decreases for two programs. The remaining 57 programs that the military services provided information on did not propose any changes to the CSB. However, we found that four programs changed requirements in 2013 without presenting the changes to the CSB for review or approval. In all four instances, the programs deferred, decreased, or modified their requirements.

We are not making recommendations in this report. We provided a draft of this product to DOD for comment. In an e-mail received on May 2, 2014, the Assistant Secretary of Defense for Acquisition stated that the department did not have any comments on the report. However, DOD provided technical comments which were incorporated into the report, as appropriate.

Military Services Consistently Held Annual Configuration Steering Boards

The military services held a CSB in 2013 for nearly all of the current MDAPs as required by statute—77 of 79 programs (approximately 97 percent). Table 1 shows the number of CSBs held in 2013 by military service.

Table 1: Number of Current Programs that Held Configuration Steering Boards in 2013

Military Service	Number of Major Defense Acquisition Programs[a]	Number of Programs that Held a Configuration Steering Board
Air Force	25	25
Army	18	18
Navy	36	34
Total	**79**	**77**

Source: GAO analysis of DOD data.

[a] The 2013 Configuration Steering Boards for the Joint Light Tactical Vehicle and the F-35 Joint Strike Fighter Aircraft were chaired by the Service Acquisition Executive of the Army and Navy, respectively, and were included in the count for each military service.

The Air Force and Army held CSBs for all of their programs in 2013, while the Navy held a CSB for all but two of its MDAPs. One of the Navy's programs, the Air and Missile Defense Radar program began development in October 2013 and is not required to complete the review until

4223 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

October 2014. The Navy cancelled its planned November 2013 CSB review of the other program, the Navy Multiband Terminal Satellite, in an effort to reduce costs and rescheduled the review for May 2014.

Each of the services combined CSBs for similar programs or held them in combination with other reviews to increase efficiency; however, this may have led to the Navy excluding required participants. For example, the Air Force and Army typically held boards for multiple similar programs at one time (i.e. aviation programs), while the Navy held boards in conjunction with annual execution or program executive office reviews. According to Navy officials, program executive office reviews were service-led meetings that included representatives from the Navy, but did not include representatives from the Joint Staff or the Office of the Secretary of Defense. Navy officials stated that any changes made during these reviews were to be sent afterwards to the Joint Staff and the Office of the Secretary of Defense for review.

CSBs Were Actively Involved in the Review of Requirements Changes and Cost and Schedule Impacts, but Not All Changes Were Brought to the Boards For Approval

CSBs reviewed and approved requirements or technical configuration changes proposed by eight programs in 2013, based on our analysis. The majority of the changes were for requirements decreases or deferrals; however, CSBs did approve some requirements increases. In addition, four programs reduced, deferred, or modified requirements in 2013 without getting approval by the CSB.

CSBs Approved Few Requirements Increases and Most Programs Identified Cost Impacts

Based on information the military services were able to provide on 65 of the 77 programs that held a CSB in 2013, the boards actively reviewed and approved requirements or technical configuration changes proposed by eight programs. The remaining 57 programs that the military services provided information on did not propose any changes to the board. We found that programs often proposed low-level system requirements changes, such as physical design requirements, as opposed to top-level requirements such as key performance parameters or key system attributes, which are considered to be critical or essential to the operation of the system. Of the eight programs whose proposals were approved by the CSB, four programs decreased or deferred requirements, two programs increased requirements, and two programs both increased and decreased requirements. Table 2 provides additional details about the eight programs whose proposals were approved by the CSB.

4224 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Table 2: Requirements and Technical Configuration Proposals Approved by Configuration Steering Boards

Program	Type of Change	Description of Change
DDG 51 Arleigh Burke Class Guided Missile Destroyer	Deferral	Deferred installing intelligence equipment until ship deployment, resulting in cost savings and minimal schedule delays.
P-8A Poseidon Multi-Mission Maritime Aircraft	Deferral	Deferred targeting and search capabilities to future increments, resulting in design change cost savings.
MQ-1C Gray Eagle Unmanned Aircraft System	Decrease	Decreased requirements for the removal and replacement of system payloads and communications data rate; no cost impacts were identified.
Warfighter Information Network-Tactical Increment 3	Decrease	Decreased key Net-Ready requirement, the ability to exchange information with the "network", and key training requirement as a result of Army budget constraints and program restructure.
AGM-88E Advanced Anti-Radiation Guided Missile	Increase	Added new technology into the system to address obsolescence, resulting in an increase in cost.
LPD 17 San Antonio Class Amphibious Transport Dock (LPD 17)	Increase	Increased security features, including containers, tubing, and locks, resulting in an increase in cost.
F-35 Joint Strike Fighter Aircraft	Increase and Decrease	Increased two requirements and decreased one requirement for allowed contaminant levels based on testing, lessons learned, and safety assessments; no cost impacts were identified.
Littoral Combat Ship	Increase and Decrease	Increased requirements to make habitability modifications and improve satellite communications, and also decreased a requirement for a stabilizing component, resulting in a net increase in cost.

Source: GAO presentation of DOD data.

As described in the table, three programs that increased requirements identified cost impacts as a result of the changes. The board approved the configuration changes and associated costs presented by the Littoral Combat Ship program, and also approved the release of engineering change order funding for the LPD 17 program to cover the cost of the changes. The CSB required the AGM-88E Advanced Anti-Radiation Guided Missile program to formally request the funding for the cost of the technology insertion and include information about the effort's return on investment. According to Navy officials, the funding was released in January 2014. The F-35 program office did not present cost and schedule impacts of its proposed changes to the CSB. According to a program official, the contractor has not yet provided a cost estimate for the changes, but these changes needed to be made for safety reasons.

Four Programs Changed Requirements Without CSB Approval

Although the CSBs were actively involved in reviewing requirements and technical configuration changes that were presented to them, we identified four programs that changed key or system requirements in 2013 without presenting the changes to the CSB for review or approval. Almost all of these changes were for requirements decreases or deferrals. Service acquisition policies allow program managers to request CSBs outside of the annual cycle, if needed, however none of these programs requested this type of meeting in 2013. Officials from most of the programs indicated that they briefed board members about the decreased requirements at the next annual meeting. A brief description of changes made to the programs is provided below.

- **Family of Beyond Line-of-Sight Terminals –** The Air Force program deleted two system-level requirements in 2013, both without CSB approval. The program did not propose these deletions to the board for approval because, according to program officials, the Air Force's requirements council had already approved them. According to program officials, both requirements related to software architecture, and were deleted

4225 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

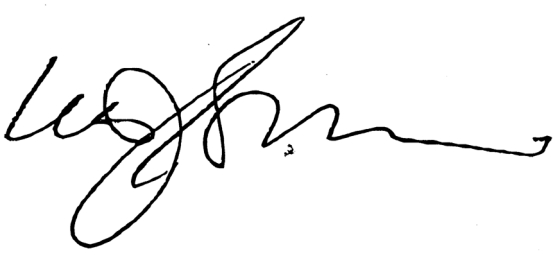
either because the program no longer needed the architecture due to technology developments or because DOD no longer used these legacy interfaces.

- **Paladin Integrated Management –** This Army program modified a key system attribute related to firing accuracy without CSB approval. The program adjusted its minimum and maximum range values upwards and downwards, respectively, based on testing results. Officials stated that the accuracy requirement adjustment did not impact the program's cost or schedule. Program officials further stated that they worked with requirements officials to receive approval for the modification and did not find the need to call special event-driven boards because everyone involved in the CSB process was already involved with the normal requirements change approval process. The program did, however, brief the CSB about the change during its 2013 annual meeting.

- **RQ-4A/B Global Hawk Unmanned Aircraft System –** In 2013, the Air Force's Global Hawk program deferred 15 system-level requirements related to the ground control station and control of the aircraft, among other things. The President's Budget for Fiscal Year 2013 divested the program's Block 30 system and eliminated related funding. Global Hawk officials stated that these deferrals were not proposed during the program's annual CSB review because they were directly related to the termination of the Block 30 aircraft.

- **Warfighter Information Network-Tactical (WIN-T) Increment 2 –** The Army's WIN-T Increment 2 program deleted a key performance parameter related to force protection. According to program officials, the program's final product will be installed on various platforms that did not have the same requirement criteria, and are beyond the program's control. The program sought and received approval for the deletion from the Joint Requirements Oversight Council in August 2013. According to program officials, the program did not propose this deletion to the board for approval because the requirements council had already approved the deletion. Program officials further stated that the program did not consider holding an event-driven CSB because the Joint Requirements Oversight Council is responsible for approving key performance parameter changes. However, program officials stated that they informed the board of the deleted requirement during the annual board meeting.

Agency Comments



We are not making recommendations in this report. We provided a draft of this product to DOD for comment. In an e-mail received on May 2, 2014, the Assistant Secretary of Defense for Acquisition stated that the department did not have any comments on the report. However, DOD provided technical comments which were incorporated into the report, as appropriate.

GAO's Mission

The Government Accountability Office, the audit, evaluation, and investigative arm of Congress, exists to support Congress in meeting its constitutional responsibilities and to help improve the performance and accountability of the federal government for the American people. GAO examines the use of public funds; evaluates federal programs and policies; and provides analyses, recommendations, and other assistance to help Congress make informed oversight, policy, and funding decisions. GAO's commitment to good government is reflected in its core values of accountability, integrity, and reliability.

Obtaining Copies of GAO Reports and Testimony

The fastest and easiest way to obtain copies of GAO documents at no cost is through GAO's website (www.gao.gov). Each weekday afternoon, GAO posts on its website newly released reports, testimony, and correspondence. To have GAO e-mail you a list of newly posted products, go to www.gao.gov and select "E-mail Updates."

Order by Phone

The price of each GAO publication reflects GAO's actual cost of production and distribution and depends on the number of pages in the publication and whether the publication is printed in color or black and white. Pricing and ordering information is posted on GAO's website, http://www.gao.gov/ordering.htm.

Place orders by calling (202) 512-6000, toll free (866) 801-7077, or TDD (202) 512-2537.

Orders may be paid for using American Express, Discover Card, MasterCard, Visa, check, or money order. Call for additional information.

Getting Our Partners Airborne

Training Air Advisors and Their Impact In-Theater

Maj Gen Michael A. Keltz, USAF

Most Americans would be surprised to learn that US Air Force (USAF) members fly Russian-made Mi-17 transport helicopters and that a few have even flown Mi-35 gunships. USAF aircrew and maintenance personnel will also soon fly and maintain the Embraer / Sierra Nevada A-29 Super Tucano light attack aircraft and a special-mission variant of the Pilatus PC-12—and will continue to do so for years to come. The origins of these programs can be traced to 2007, when the Department of Defense (DOD) developed a plan to build airpower capabilities in the Iraqi and Afghan air forces. For Afghanistan, the concept of operations proposed the acquisition of 149

4235 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

rotary- and fixed-wing aircraft for training and a variety of operational missions. This proposal identified the need for an initial contingent of 600 USAF personnel—a number that would increase with growing demand in Afghanistan—to train and advise Iraqi and Afghan partners. Accordingly, the directive called for a capability to train USAF personnel in the air-advising mission prior to deployment. Although Air Force Special Operations Command had been providing this type of training for special operations forces (SOF), no such training existed for these conventional General Purpose Forces (GPF) Airmen. Existing ground-centric, predeployment training centers and SOF aviation-related training venues were at capacity. Consequently, in March 2007, the chief of staff of the Air Force directed Air Education and Training Command (AETC) to establish a permanent AETC-led predeployment training detachment, the Air Advisor Academy (AAA), to prepare air advisors to serve in this capacity.[1]

The Iraqi Air Force flies the C-208B as a flying training platform. Modified versions perform special missions. (From "AC-208 Combat Caravan Light Attack Aircraft, Iraq," airforce-technology.com, http://www.airforce-technology.com/projects/ac-208-combat-caravan/.)

4236 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Air Advisor Academy

Since the inception of the AAA in 2007, this AETC schoolhouse has educated and trained more than 4,300 students. Now fully operational at Joint Base McGuire-Dix-Lakehurst in New Jersey, the AAA has the capacity to train up to 1,500 students per year, producing 1,227 graduates in 2013. The school provides education and training in three areas: (1) air-advising core skills; (2) language, region, and culture; and (3) advanced force-protection skills, referred to as "fieldcraft." AETC offers eight different AAA training courses for Airmen deploying to permissive, uncertain, and hostile environments in any region across the globe; furthermore, it can tailor these courses in accordance with particular customer requirements. Airmen preparing to serve as aircrew and maintenance air advisors in Iraq and Afghanistan must complete a five-week hostile-environment course.

Even though this article discusses aircrew and maintenance air advisors, it is important to note that the AAA trains Airmen who will advise foreign partners in nearly every USAF career field. In fact, roughly 75 percent of Airmen who serve as air advisors come from the many other USAF career fields. Similarly, this article focuses on Iraq and Afghanistan, but the school trains Airmen preparing for air-advising activities in every geographic combatant command (GCC). Indeed, AAA education and training are on the rise as the demand for air advisors grows across each GCC. Gen Mark A. Welsh, the USAF chief of staff, explained in a June 2013 interview that "there are lots of other combatant commands that want the things that we offer who haven't gotten them for a while." General Welsh cited "partnership-building capability engagements," among other USAF capabilities, as a requirement across the GCCs that "is not going away; it's just going to shift."[2] Current unconstrained calculations for the next five years indicate that the number of Airmen who need training to perform air-advising and other security-cooperation activities in countries other than Iraq and Afghanistan could meet or even exceed the school's current capacity.[3]

4237 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Projections indicate that the demand for air advisors in Afghanistan will remain long after the planned termination of US and coalition combat operations at the end of 2014. In its July 2013 *Report on Progress toward Security and Stability in Afghanistan* to Congress, the DOD assessed that Afghan National Security Forces (ANSF) will "need continued assistance and combat support through the end of the ISAF [International Security Assistance Force] mandate in December 2014; beyond then it will still require substantial training, advising and assistance—including financial support—to address ongoing shortcomings." The latter include "more complex and technologically advanced capabilities that will be fielded, such as . . . air support." More specifically, the DOD found that "ANSF components responsible for these more complex tasks, particularly air operations, will not be capable of fully independent operations by December 2014," citing long-term challenges in more sophisticated aviation career fields.[4] In a news conference on 30 July 2013 aligned with the release of this report, Dr. Peter Lavoy, acting assistant secretary of defense for Asian and Pacific security affairs, elaborated on this assessment: "We envision that it will take a period of time before they can adequately fully have sovereign ownership of all those skill sets, including well beyond the 2014 date."[5] In the June 2013 interview, General Welsh voiced a similar view, asserting that the Afghan Air Force (AAF) lacks "people who are trained to maintain an air force over time" and offered that the USAF "can help them with that. But it's going to be a few more years before they're there, in our estimation."[6] Accordingly, Kristina Wong projected in a June 2013 *Washington Times* article that most of the 940 coalition advisors currently building the AAF will remain through 2017 and that a smaller number could continue advising Afghans until 2024.[7]

Training for Aircrew and Maintenance Air Advisors

In addition to AAA courses, aircrew and maintenance air advisors must have specific training in the partner nation (PN) aircraft they will operate and maintain. Once trained, aircrew personnel receive formal

4238 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

flight evaluations to gain certification in the operation of these platforms. When the PN aircraft is also flown in the USAF, the major command (MAJCOM) responsible for the training typically manages this portion of air-advising training. In the case of non-USAF aircraft, such as the Mi-17, the aircrew and maintenance training is managed by AETC Headquarters' Special Missions Division (HQ AETC/A3Q) in the Directorate of Intelligence, Operations, and Nuclear Integration at Joint Base San Antonio–Randolph in San Antonio, Texas. To execute these responsibilities, the division works with the theater—US Central Command in the case of Iraq and Afghanistan—to establish and validate the associated training requirements. HQ AETC/A3Q then establishes the USAF program that will support this requirement, develops a DOD or contracted training solution, initiates the contracting process when applicable, and—once the contract is awarded—oversees execution of the contracted training. Additionally, the division develops the syllabus that will guide the training, schedules individuals for training, and manages the associated student pipeline. HQ AETC/A3Q also manages standardization/evaluation programs for each of these non-USAF aircraft. Individuals assigned to the division conduct flight evaluations to certify aircrew members in the operation of these aircraft. Bringing these responsibilities full circle, HQ AETC/A3Q performs assessments of the air-advising programs in-theater and uses feedback from these visits to make necessary changes to air-advising education and training.

Furthermore, AETC's Special Missions Division supplies MAJCOM-level management and oversight of GPF air-advising education and training conducted at the AAA. Centrally managing these programs from a single office makes perfect sense because each is inextricably linked to both the air-advising mission and each other. Since AETC is the lead MAJCOM for air-advising education and training, non-USAF aircrew and maintenance training, flying training, technical training, and expeditionary skills training, it's also logical that the AAA and associated aircrew/maintenance training fall under that command. Since the inception of this air-advising aircrew and maintenance training

4239 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

program in 2007, AETC—with HQ AETC/A3Q in the lead—has managed the training of a total of 846 aircrew and maintenance professionals in 12 aircraft types at a rate of roughly 150 trainees per year. The program has had a substantial impact in Iraq and Afghanistan and is poised to do even more across the globe in the years ahead.

An Afghan Air Force Mi-35 gunship awaits tasking at Kabul International Airport, Afghanistan, on 13 February 2010. Two USAF pilots served as air advisors in Afghan Mi-35s during 2010 and 2011.

Rotary-Wing Air-Advising Programs

After the Soviet-Afghan war in the 1980s, the Soviet Union left the Soviet-backed Afghan government with a fleet of over 400 military aircraft, including a large number of Soviet-made helicopters. Years of

4240 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

fighting within Afghanistan during the 1990s and the US response to the terrorist attacks of 11 September 2001 left the AAF in shambles. By 2007 the Afghan military had only 20 aircraft in its inventory, mostly Mi-17s and Mi-35s.[8] As a direct result of US security assistance and US-led air-advising programs in Afghanistan, the AAF now consists of approximately 100 aircraft. The fleet includes 48 Mi-17s, six Mi-35 attack helicopters, 26 Cessna 208B (C-208B) Grand Caravan fixed-wing trainers/airlifters, six Cessna 182 (C-182) fixed-wing trainers, and six MD-530 rotary-wing trainers.[9] Two USAF pilots served as Mi-35 air advisors in 2010 and 2011, helping the AAF further develop this preexisting capability.[10] The AAF had 6,277 personnel in March 2013, and—as C-130Hs, A-29s, PC-12s, and more Mi-17s are added to the fold—projections indicate it will have 140 aircraft and 8,000 personnel by 2016.[11] According to the DOD's *Report on Progress*, "The Afghan Air Force faces a number of challenges—particularly recruiting and training personnel to operate and maintain the fleet—and is not expected to be fully mission capable until at least 2018."[12] To meet this objective, the USAF must have a sustained and fully funded air-advising program during this time frame.

USAF air advisors train, advise, and assist Afghan counterparts in Mi-17 operations and maintenance; moreover, the advisors' duties include combat missions with Afghan crews. Prior to deploying, these USAF crew members and maintainers attend AETC's Mi-17 training courses for aircrew and maintenance air advisors. Concord XXI Inc. provides a two-week Mi-17 simulator training course in Daleville, Alabama, during which pilots and flight engineers complete 40 hours of academics and 10 simulator hours, and the flight engineers undergo an evaluation in the simulator. After finishing the course, pilots attend six weeks of Mi-17 flying training in Destin, Florida, conducted by Vertol Systems Company Inc. This course consists of 40 hours of ground academics, 35 hours of flight training, and two formal flight evaluations. Flight engineers attend a four-week course in Destin that includes 25 flying hours. USAF maintenance personnel preparing to deploy as air advisors attend a three-week US Army Mi-17 maintenance course at

4241 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Fort Rucker, Alabama, that emphasizes general aircraft familiarization and involves 40 hours of academics and 80 hours of hands-on training. Typically, as many as 25 USAF pilots, six flight engineers, and 48 maintenance personnel are trained each year to perform air-advising duties in the Mi-17. Twelve pilots, 17 flight engineers, and 30 maintainers completed training in 2013.

An Mi-17 search and rescue, humanitarian assistance, and disaster-relief mission conducted on 28–29 July 2010 in northeastern Afghanistan demonstrates one impact not often considered in conjunction with air advising. Massive flooding led local Afghan government authorities to request assistance from Brig Gen Muhammed Barat, the AAF's Kabul Air Wing commander, in the early morning of 28 July 2010.[13] Lt Col Greg Roberts, a career USAF rescue helicopter pilot, was serving at the time as General Barat's air advisor and commander of the USAF air-advising squadron in Kabul.[14] General Barat and Lieutenant Colonel Roberts immediately assembled a team of AAF crew members and USAF air advisors to respond to a humanitarian disaster unfolding in one of the most high-threat, insurgent-laden regions of Afghanistan. In just two AAF Mi-17 helicopters, this team rescued an astonishing 2,080 Afghans over the next two days—the largest two-ship helicopter rescue in USAF history.[15] Arming Afghans with the capacity to conduct humanitarian missions of this type across their country will drastically increase the legitimacy of the ANSF and the Afghan government as a whole. Ultimately, helicopter missions saving Afghans will have a far more powerful effect on the hearts and minds of the Afghan people—and the efficacy of the Taliban, for that matter—than any other effect of direct air combat. If a handful of Afghans and air advisors with two Mi-17s can have such an impact in two days, then one can only imagine what a fully trained and operational AAF will be able to do.[16]

4242 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

An Afghan Air Force officer who flew on board the Mi-17s rescues a child during the daring two-day operation. (From Lt Col Gregory A. Roberts, "Flight Lead Narrative for Afghan Rescue 705 Flight Operations, 28–29 Jul 2010," 438th Air Expeditionary Wing, 6 August 2010, with updates 24 January 2011 and 1 March 2011.)

As the AAF builds on such experiences, the DOD's *Report on Progress* observed that "the AAF is increasingly capable of carrying out a range of operations" and cited examples of its growing effect.[17] From 15 to 18 November 2012, AAF Mi-17s supported Afghan border police who were providing supplies to local villages in a contested area of southern Afghanistan—"possibly the first time these villages had seen GIRoA [Government of the Islamic Republic of Afghanistan] forces, let alone AAF helicopters, delivering humanitarian aid."[18] In fact, AAF Mi-17 operations have advanced to the point where Afghan crews routinely conduct resupply, casualty evacuation (CASEVAC), and passenger-transport missions across the country without US or coalition air advisors on board.[19] In partnership with coalition and Afghan ground forces, Mi-17s now conduct more sophisticated air-assault operations as well.[20] The same report, however, projected that "the 86 Mi-17 helicopters pro-

4243 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

grammed for the post-2014 AAF fleet will meet only minimal operational requirements."[21] USAF air advisors will necessarily continue to assist and advise their Afghan counterparts as the AAF develops its fleet of Mi-17s and builds on this progress.

Fixed-Wing Air-Advising Programs

C-172 and T-6

Beyond the Mi-17 program in Afghanistan, AETC-trained USAF air advisors also offered years of assistance to the Iraqi Air Force (IqAF) in the development of a fixed-wing pilot-training program. At its inception, this program consisted of six months of primary flight training in the C-172 and six months of advanced flight training in the C-208B. USAF air advisors served as instructors in both aircraft. The Beechcraft T-6 Texan II is now used for primary flight training in Iraq, and USAF air advisors advise the IqAF on T-6 maintenance practices. USAF air advisors train and advise foreign counterparts to enable the PN air forces they represent to perform, over time, their roles and responsibilities independent of US assistance. This approach is now mature in Iraq, and if the United States stays the course, the air-advising model can prove successful in Afghanistan as well.

C-182 and C-208B

As in Iraq, pilot training in the AAF consists of two phases: the first in the C-182 and the second in the C-208B. USAF active-duty and contracted air advisors instruct in both aircraft. HQ AETC/A3Q is charged with training the active-duty air advisors involved in these and other non-USAF aircraft programs. The Air Force Security Assistance Training Squadron, assigned to the Headquarters AETC International Affairs Directorate at Joint Base San Antonio–Randolph, manages USAF contracts that deploy civilian instructors who support some of these same programs. To prepare USAF air advisors en route to Afghanistan, the

4244 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Spartan College of Aeronautics and Technology in Tulsa, Oklahoma, provides C-182 and C-208B aircrew and maintenance training. Spartan previously offered the C-172 training as well. The 15-day C-182 air-advisor pilot course consists of approximately 10 hours of ground academics, 10 hours of flight training, and a flight evaluation. The C-208B pilot course lasts 20 days, with 10 hours of ground academics, 12 hours of cockpit procedural training, 20 hours of flight training, and a flight evaluation. Roughly half of the 15-day familiarization training for the maintenance air advisors consists of hands-on experience.

The training that USAF air advisors provide in the various Afghan airframes has begun to bear fruit. Three AAF classes have completed their pilot training in Afghanistan and, on 23 June 2013, the fourth class began the C-208B phase of training.[22] On 20 May 2013, an Afghan C-208B crew flew a badly wounded Afghan soldier from Kandahar to a hospital in Kabul. A USAF air advisor participated in the operation, but this mission marked only the second time that AAF personnel had planned and led a real-world CASEVAC mission.[23] In fact, the AAF has recently reached the point where it has begun flying operational missions without the assistance of air advisors. On 25 June 2013, two Afghan lieutenants trained by USAF air advisors completed the first all-Afghan C-208B operational flight, airlifting 16 passengers—including four local governors.[24]

4245 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Members of the Afghan Air Force's Security Forces Quick Reaction Force of the Kabul Air Wing unload from an Mi-17 and practice insertion procedures during an exercise on 27 March 2013. (From Capt Anastasia Wasem, "Afghan Air Force Conducts Multi-Aircraft, Multi-Capability Exercise," US Air Forces Central Command, 1 April 2013, http://www.afcent.af.mil/news/story.asp?id=123342416.)

Additionally, Afghan forces have begun conducting exercises involving both fixed- and rotary-wing missions. On 27 March 2013, the AAF conducted its first combined training exercise, flying Afghan Mi-35s and Mi-17s in an air-assault capacity and C-208Bs in a CASEVAC role.[25] The Mi-17s inserted and extracted Afghan troops, Mi-35s cleared landing sites and flew armed overwatch, and C-208Bs transported patients. USAF air advisors trained, advised, and assisted the AAF in developing these operational capabilities. These exercises and other ongoing training efforts have stimulated progress on the battlefield. In support of a major Afghan National Army operation in northeastern Afghanistan in the spring of 2013, Mi-17s and C-208Bs flew CASEVAC and battlefield circulation missions.[26] In fact, the AAF increased its CASEVAC mis-

4246 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

sions by 34 percent from February to June 2013.[27] Such air operations allow the Afghans to take the lead, reducing the ANSF's dependence on US and coalition forces. As a result of the air-advising effort, the United States has in turn begun reducing a commensurate portion of direct air support to Afghan ground forces. In a very real and measurable way, then, air advising allows US military forces in Afghanistan to implement the Obama administration's plan to transition combat operations to Afghan forces by the end of 2014.[28]

Three Afghan Air Force pilots receive recognition after completing aircraft commander upgrade training. Following a year of flying with USAF air advisors, two of these pilots flew the first all-Afghan C-208B mission on 25 June 2013. (From "Major Milestone Achieved As AAF Aircraft Commanders Are Certified and Fly First All Afghan C-208 Mission at Shindand AB," *NATO Training Mission Afghanistan Storyboard*, 838th Air Expeditionary Advisory Group, 25 June 2013.)

4247 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Aircraft on the Horizon

Even though projections call for the end of US combat operations in less than a year, the air-advising mission will remain necessary for years to come. Three new Afghan aircraft programs that will need an enduring air-advisor mission in Afghanistan—and will ultimately allow the AAF to stand on its own—include the C-130H, the light air support (LAS) A-29 Super Tucano, and the PC-12. The ANSF is currently dependent on US and coalition capabilities such as medium airlift; special-missions support; intelligence, surveillance, and reconnaissance (ISR); and fixed-wing weapons employment. The development of Afghan-appropriate capabilities in each of these areas is critical. The C-130H, A-29, and PC-12 have been selected to perform these roles, thus prompting the need for USAF air advisors and associated preparatory training in all three airframes. HQ AETC/A3Q will play a key role in the development, implementation, and management of USAF A-29 and PC-12 training programs and will assist in preparing C-130H air advisors.

C-130H

To meet a pressing requirement for a medium-airlift capability, Ashton B. Carter, the US deputy secretary of defense, directed the USAF in January 2013 to provide the AAF with four C-130Hs and associated training.[29] The first two aircraft arrived on 9 October 2013, and delivery of the last two is scheduled for November 2014.[30] The first group of Afghan C-130H pilots began training in the United States in May 2013.[31] Assisting the AAF in fully developing this new program will require a USAF air-advising mission in Afghanistan after 2014. According to the DOD's *Report on Progress*, the new C-130Hs "provide an initial capability to do inter-theater lift that will take several years to mature."[32] USAF aircrews/maintainers with prior C-130H experience will comprise the bulk of initial air advisors, and the USAF's Air Mobility Command will likely provide any necessary training for the aircrew and maintenance personnel. On 14 August 2013, the first group of 31

4248 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

USAF maintainers preparing to assist the AAF with the new C-130H program completed the necessary predeployment training at the AAA.

A-29

Brazilian Embraer Defense and Security, in cooperation with the US-based Sierra Nevada Corporation, was selected on 27 February 2013 to supply the AAF with 20 A-29 Super Tucanos, training for AAF aircrew and maintenance personnel, and associated logistical support.[33] Sierra Nevada will also train USAF air advisors who will in turn train and advise the AAF. This air-advisor training is scheduled to begin in the fall of 2014. The first A-29s should be available in September 2014, and at that point, plans call for delivering two aircraft per month.[34] The USAF intends to deploy air advisors to Afghanistan to assist Afghan counterparts as they build the organizations and infrastructure required to support this more sophisticated weapons system. The DOD reported that the new A-29 LAS program will "provide the AAF with the capability to conduct air interdiction, armed reconnaissance, air-to-ground support, combat search and rescue, border patrol, and aerial escort missions."[35] To train the AAF to perform these missions adequately, officials project an incremental training approach that includes US aircrew and maintenance air advisors for years to come. In fact, "the full employment of CAS [close air support] capability is not expected until sometime post-2018."[36]

Although this new USAF A-29 LAS program focuses on Afghanistan, it brings with it some extraordinary opportunities elsewhere. Over the past 70 years, the Inter-American Air Forces Academy (IAAFA), located at Joint Base San Antonio–Lackland, has played a central role in USAF security cooperation and engagement efforts across the Western Hemisphere. This AETC organization has trained more than 45,000 Latin Americans in a variety of mission areas, including aircraft operations and maintenance.[37] Meanwhile, the Brazilian-built Super Tucano is rapidly becoming the light attack weapons system of choice across much of Latin America.[38] As the region's air forces transition to the Su-

4249 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

per Tucano, it will become increasingly important for IAAFA instructors to gain knowledge and expertise in the operation and maintenance of this airframe—and initial steps have been taken toward that end. During a June 2013 visit to the IAAFA, representatives from Embraer and Sierra Nevada delivered A-29 technical manuals. The IAAFA plans to use these materials to incorporate A-29 checklists and procedures into six of its maintenance courses.[39]

The A-29 air-advising mission allows the IAAFA to further improve this effort. As A-29 aircrew and maintenance air advisors to the AAF, USAF personnel will acquire substantial knowledge of A-29 operations and maintenance. Further, they will gain unique combat-related A-29 experience that will greatly assist the IAAFA and its faculty as the academy continues to engage a region moving decidedly toward the Super Tucano. This tie between Afghanistan and the IAAFA mission is instructive insofar as it demonstrates quite poignantly that air advising and security cooperation are more widely applicable beyond the borders of Iraq and Afghanistan. It also shows the critical role that AETC organizations—such as the Air Force Security Assistance Training Squadron; HQ AETC/A3Q; the AAA; and, potentially, the IAAFA—play in institutionalizing the knowledge and experience acquired in Iraq and Afghanistan for use in other countries and GCCs around the world.

During current military operations in Afghanistan, US and other coalition aircraft flying close air support missions receive targeting information and clearance to expend munitions from US and coalition joint terminal attack controllers (JTAC). Prior to deployment to Afghanistan, US controllers complete a rigorous program that often includes training with actual aircraft that will conduct combat operations in that country. It is also quite valuable for the aircrews flying these aircraft to train with the same JTACs who will direct air-to-ground operations intheater. The aircraft and aircrews, however, have multiple other predeployment training requirements; consequently, aircraft availability for JTAC training is often problematic. Because plans call for A-29 air-advising training to take place in the United States, the pilots of these

4250 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

aircraft may be available for JTAC training. If availability and contractual agreements allow, this training would prove mutually beneficial for pilots and JTACs alike as A-29s take flight in Afghanistan. Over time, A-29s will begin combat operations in Afghanistan, and the training that JTACs and air advisors receive stateside could be put to good use downrange.

KA-350/AC-208B/PC-12

In years past, HQ AETC/A3Q managed two air-advising aircrew and maintenance programs supporting the IqAF that demonstrate the capacity for air-advising efforts to reach their desired end state. A military variant of the Hawker Beechcraft King Air 350 light transport aircraft, the KA-350ER-ISR was introduced into the IqAF in July 2008 to serve in an aerial reconnaissance role.[40] Hawker Beechcraft offered KA-350 maintenance-familiarization training in Wichita, Kansas, to support this IqAF advising mission. Pilots received KA-350 simulator training in Orlando, Florida, and then flew US Navy T-44s with a compatible avionics suite at Naval Air Station Kingsville in Corpus Christi, Texas. Similar to the MC-12W Liberty flown by the USAF in Afghanistan, the modified KA-350 gives the IqAF the ISR capabilities necessary to detect and deter insurgent activity.[41] USAF air advisors launched the KA-350 program and, after it matured, transitioned operations and maintenance to full control of the IqAF.

4251 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Photo courtesy Sgt Brandon Bolick, USA

An Iraqi Air Force AC-208B Combat Caravan fires a Hellfire missile on 8 November 2010 and scores a direct hit on an Aziziyah Training Range target south of Baghdad. (From MSgt Mike Edwards, "Iraqi Airmen Demonstrate Operational Capabilities in Hellfire Exercise," *Inside Af.Mil*, 2 December 2010, http://www.af.mil/news/story.asp?id=123233035.)

The same occurred with a special-missions variant of the C-208B. Three of these aircraft, modified to serve in an ISR capacity, were delivered to the IqAF in 2007. The following year, Alliant Techsystems Inc., a defense company in Fort Worth, Texas, began modifying three C-208Bs to carry and employ the AGM-114M/K Hellfire missile.[42] Alliant delivered the first of these aircraft in December 2008 and the last in November 2009. An IqAF AC-208B aircrew first fired a Hellfire missile on a bombing range near Al Asad Air Base on 4 November 2009. The following year, on 8 November, Iraqis fired a second missile in conjunction with the first Iraqi-run live-fire missile-training exercise since the time preceding Operation Iraqi Freedom in 2003.[43] USAF air advisors played an active role in advancing IqAF capabilities to this point. The

4252 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

third live employment, on 23 March 2011, further validated the USAF's air-advising mission. An Iraqi special operations forward air controller directed this AC-208B launch, which occurred as part of an increasingly sophisticated scenario.[44] Adding this aircraft to the inventory—and training its crews and maintainers—has enabled the IqAF to better conduct counterinsurgency operations.

These two programs might be considered predecessors of the PC-12 program now on the rise in Afghanistan. An Afghan Special Mission Wing (SMW), established in July 2012, provides air support to the Afghan special forces' counterterrorism and counternarcotics mission.[45] Up to this point, those special forces and the new SMW, together with 30 aging Mi-17s and 180 personnel, have relied heavily on US support to the special operations mission.[46] To enable transition to Afghan air support of special missions, the DOD recently awarded two contracts for a total of 48 new SMW aircraft. Sierra Nevada will supply 18 specially modified PC-12s, and Russian-based Rosoboronexport will deliver 30 new Mi-17s that will replace the existing fleet.[47]

Training and advising Afghan special operations aircrews and maintainers will take time. The new wing plans to have 188 pilots to fly its projected fleet of 48 aircraft; it had 42 pilots as of January 2013. Only seven of them were fully qualified to fly with night vision goggles. The SMW includes a total of 32 crew chiefs / flight engineers but needs 143. Of the 385 Afghan maintenance personnel required, the wing had only 86.[48] Working in conjunction with the theater, HQ AETC/A3Q is developing a plan to help the Afghans fill these personnel shortfalls by training and advising the SMW's aircrew and maintenance force. In addition to the Mi-17 program already discussed, the first USAF aircrew preparing to serve as PC-12 air advisors graduated from training in November and December of 2013. Once again, HQ AETC/A3Q will be responsible for training the active-duty air advisors, and Air Force Security Assistance Training will manage the contracted PC-12 instructors.

4253 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Conclusion / The Way Ahead

Multiple, tangible benefits accrue to these air-advising aircrew and maintenance programs in Iraq and Afghanistan. First, USAF air advisors played an important role in enabling an orderly departure from Iraq at the end of 2011 and will remain central to the Obama administration's plan to transition military operations to Afghan control. Simply stated, a viable air force for Afghanistan depends upon the continued support of USAF air advisors. Without an adequate airpower capability, Afghan ground forces either will not have the capacity to maintain security or will require dedicated US and coalition air support beyond 2014—neither of which seems a practical option at present.

More specifically, without AAA and HQ AETC/A3Q support, the Afghan C-130H, A-29, and PC-12 programs will never get off the ground. Nicole Finch and Lt Col Peter Garretson observed that US engagement strategy "cannot consist simply of selling or giving a partner nation equipment and then leaving. The goal of improving a partner nation's aviation enterprise starts long before any equipment is procured or delivered and continues after any equipment is fielded."[49] Accordingly, cutting short the air-advising mission in Afghanistan would likely leave Afghans with new aircraft they cannot adequately operate and maintain. Additionally, the current Mi-17, C-182, and C-208B programs—which are gaining momentum and beginning to show some measurable results—will likely stall without continued and consistent support from USAF air advisors. Similarly, AAF and SMW missions such as pilot training, mobility, CASEVAC, light attack, and air support for special missions would falter. Continuing the USAF air-advising mission, then, offers the only reasonable USAF method by which Afghan forces can reduce current dependence on US and coalition capabilities and ultimately assume control in each of these areas.

The benefit of air advising is not isolated to Iraq and Afghanistan. With AETC in the lead, the USAF has institutionalized GPF air-advising training for aircrew and maintenance personnel and is now poised to apply that model elsewhere. As previously noted, robust air-advising

4254 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

experience and knowledge of A-29 Super Tucano combat operations and maintenance in Afghanistan will posture the service to train and advise PNs at the IAAFA, across Latin America, and wherever these aircraft may be flown. As budgets decrease and sequestration takes full effect, this low-cost alternative to persistent US military presence abroad allows us to further our national security interests around the world and continue to assist our partners, like Afghanistan, with a substantially reduced financial burden and US military footprint. In sum, USAF air advising will allow us to transition responsibility over time to the AAF as we build the airpower capacity of other PNs around the globe. ✪

Maj Gen Michael A. Keltz, USAF

Major General Keltz (USAFA; MS, Troy State University; MSS, Air War College) is the director of intelligence, operations, and nuclear integration, Headquarters Air Education and Training Command, Joint Base San Antonio–Randolph, Texas. He is responsible for developing policies and programming resources for Air Force technical and aircrew training programs, which include air advising and associated aircrew and maintenance education and training. General Keltz has flown combat and contingency operations on AC-130H, MC-130E, MC-130H, and AC-130U gunships and Combat Talons in Grenada, El Salvador, Panama, and Sierra Leone and in Operations Desert Storm and Provide Comfort. During Operations Enduring Freedom and Iraqi Freedom, he was the air component commander for several classified joint task forces in Iraq and Afghanistan. General Keltz has commanded a special operations squadron, a special mission group in Iraq and Afghanistan, the 386th Air Expeditionary Wing in Southwest Asia, and the 607th Air and Space Operations Center at Osan Air Base, South Korea. The general is a command pilot with more than 4,000 hours, including over 300 combat and contingency sorties in AC-130, C-130E, and MC-130 aircraft.

Joint Intelligence, Surveillance, and Reconnaissance in Contested Airspace

Dr. Robert P. Haffa Jr.
Anand Datla

Despite unprecedented success with intelligence, surveillance, and reconnaissance (ISR) networks put in place over Iraq and Afghanistan during the last decade, the joint force has yet to come to grips with the challenges and range of possible options to employ ISR platforms in contested airspace.[1] The Department of Defense ISR Task Force that supported innovations such as Project Liberty and

4259 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

the battlefield airborne communications node in countering insurgencies in Southwest Asia and the Middle East has not yet addressed either the new strategic concepts or the operational challenges inherent in an AirSea Battle in the Western Pacific or the Persian Gulf in an antiaccess/area-denial (A2/AD) environment.[2]

This article seeks to define the attributes of a family of airborne ISR systems required to operate in nonpermissive military environments. It assumes that despite solid progress in integrating ISR into uncontested airspace, these systems, for the most part, will not prove adequate in future contingencies in which the adversary contests the airspace over a vital region. To help expand the scope of options for ISR systems to operate effectively under these conditions, the article identifies operational factors in Iraq and Afghanistan that led to an integrated, joint ISR system of systems. In so doing, it becomes apparent that the force mix of platforms and sensors fielded to support these conflicts is unlikely to be the right system for an emerging security environment characterized by problematic access and the denial of key bases, ports, and lines of communication enabling power projection. When force planners analyze the plausible contingencies facing US armed forces in the future, they find that an ISR network designed for operation in permissive airspace will be quickly stretched to failure.

The article first reviews the ISR network that proved so successful in uncontested airspace in terms of platforms, sensors, and integration systems (command, control, communications, and computers used for processing data). It then examines the tasking declared in *Sustaining U.S. Global Leadership: Priorities for 21st Century Defense*, inferring from that document and follow-on joint guidance the requirements for a future ISR family of systems.[3] Finally, the article suggests a course of action through investment in ISR platforms, sensors, and system integration that might successfully underwrite this strategic guidance.

4260 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

ISR in Uncontested Airspace: Platforms, Sensors, Integration

Airborne ISR assets deployed to Iraq and Afghanistan had the good fortune to operate in essentially uncontested airspace in support of counterinsurgency and counterterror operations. Much of that airborne ISR network consisted of unmanned aerial vehicles (UAV) because of their long dwell time, improved sensors, enhanced connectivity, and precision strike capability. By using more than a platform-centric approach, however, the United States successfully created a family of systems during these conflicts that integrated sensors and command and control (C2) systems to prosecute the wars against a mobile and clandestine foe.

The principal airborne ISR platforms employed in Iraq and Afghanistan were UAVs that evolved from use of the Predator drone during the North Atlantic Treaty Organization's air war over the Balkans in the late 1990s. Although the Predator brought newfound capability in its ability to persist over an area of interest and relay video to the air component commander, "it couldn't . . . deliver target-quality mensurated coordinates or designate targets for other aircraft to strike."[4] Furthermore, the Predator may have brought with it the second-order consequence of gluing too many humans in the chain of command to the video screen, forming long lines of intelligence analysts waiting for their opportunity to watch the real-time show from the battlefield and, as a result, slowing decision making. For example, the attack on Abu Musab al-Zarqawi, the al-Qaeda leader in Iraq, was said to have taken 600 hours of Predator time and thousands of hours of analyst time to facilitate a strike executed in a matter of minutes. Nevertheless, Predator ushered in a new era in situational awareness (SA) and inspired a revolution in coupling ISR with strike when it and its follow-on, the Reaper, were mated with the Hellfire antitank missile. That unmanned hunter-killer concept is one of the most important of all military capabilities—a lesson identified—that will carry forward as the United States faces more sophisticated adversaries in the future.

4261 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

However, Predator and Reaper had relatively narrow fields of view. Therefore, the unmanned, high-flying Global Hawk became particularly valuable to combat commanders owing to its ability to survey large geographic areas from an altitude of 60,000 feet. The United States also deployed in Afghanistan a classified, stealthy remotely piloted aircraft—once referred to as the "Beast of Kandahar"—since identified as the Sentinel, designed and deployed as a tactical reconnaissance asset. Unfortunately, this UAV surrendered its cloak of secrecy when it crash-landed over Iranian territory.[5]

Not all airborne ISR platforms used in Iraq and Afghanistan were unmanned. The MC-12 Liberty, an augmented version of the turbo-propelled King Air 350, was developed and fielded rapidly to focus on improvised explosive devices (IED) in Iraq. By cross-cueing full motion video (FMV), signals intelligence (SIGINT), and backtracking software, the Liberty system could determine not only the location of IEDs but also the events leading to their roadside insertion. Of course, the United States also deployed its more traditional manned ISR platforms to support conventional and counterinsurgency operations in Iraq and Afghanistan, such as the C-135-based capabilities of the Rivet Joint for SIGINT, the Joint Surveillance Target Attack Radar System aircraft for accurate radar imagery, ground-moving target indications and battle management, and the venerable U-2 for photo imagery. These aircraft were unimpeded by enemy air defenses in their ISR operations along and within uncontested airspace.

We should also note the term *nontraditional ISR*, which refers to the use of sensor systems such as targeting pods on manned fighter aircraft that, although not designed for ISR operations, proved very useful in contributing to battlespace awareness in these unconventional campaigns. Examples include F-18s and F-15s collecting imagery with targeting pods, F-16CJs designed for countering surface-to-air missiles collecting SIGINT, and AC-130s using video capabilities to monitor facilities of interest.[6] Such imagery has the advantage of being downloaded and transmitted over data links to the war fighter in near real

4262 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

time or simply returned to a bank of stored ISR data for processing and disseminating in a less time-sensitive environment.

Similar to the challenges facing platforms in low-intensity conflict, ISR sensors had to be adapted to concentrate on an unconventional adversary. Perhaps the most innovative—and arguably the most valuable—application was the use of FMV. Coupled with the persistence of platforms that could loiter for long periods of time, FMV could distinguish friend from foe on the ground and avoid collateral damage in the event of an attack. Prominent here were the multispectral targeting systems used by the Predator and Reaper drones, employing automated tracking, color, fused images, and electronic zoom.[7] To enlarge the field of view and allow a single aircraft to provide coverage of multiple targets, the "Gorgon Stare" system was designed to augment the FMV capability by adding 10 separate electro-optical (EO) and infrared (IR) sensors to offer a single wide-area perspective over a four-kilometer-square area. On the Project Liberty MC-12s, an IR pointer allowed the aircrew to designate an object to troops on the ground.

The sensors on these manned and unmanned systems were developed specifically for the unconventional, land-based target set in Iraq and Afghanistan. The Global Hawk, developed originally as a replacement for the manned U-2 in a strategic surveillance role, needed additional modification. Block 20 Global Hawks were equipped primarily for imagery intelligence and were later modified to serve as battlefield communications nodes. Block 30 Global Hawk aircraft acted as multispectral platforms with EO, IR, synthetic aperture radar, and SIGINT sensors. At its high-altitude, over-the-battlefield position and with its long endurance, Global Hawk could cross-cue, verify, and link similar sensors and systems operated by manned standoff ISR platforms.

Other ISR force multipliers included the targeting pods carried on tactical fighters—the so-called nontraditional ISR platforms. These pods contained high-resolution, forward-looking IR sensors displaying an image with a wide-angle search capability and a narrow field of view to acquire battlefield-sized targets. These images could be down-

4263 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

linked in streaming video to forward-deployed ground forces in a form of ISR close air support. Because of this innovation, nontraditional ISR was often specified as a fighter's primary task in the daily air tasking order and coordinated with UAV operations to supply long dwell time when needed and rapid reaction as necessary.[8]

Management and integration of these platforms and sensors have evolved over the last decade, and each of these airborne ISR systems has been adapted to facilitate real-time C2 in support of the war fighter. Unfortunately, as is often the case in individual systems, the C2 network put in place is stovepiped from platform and sensor to a specific user and service-specific distributed ground station, thus failing to cross the air, sea, and land domains and include joint customers seeking essential elements of information.

All of these ISR systems shared the objective of informing ground commanders and increasing their SA within a mobile and complex battlespace. As the initial air operations plan for Operation Enduring Freedom unfolded in late 2001, links between the Predator and AC-130U gunships were established using an omnidirectional C-band antenna. That innovation quickly led to sending Predator video to troops on the ground through a Remotely Operated Video Enhanced Receiver system, eventually supporting video feeds from multiple UAVs and downsized to handheld versions carried by troops on the ground.[9]

The object of Task Force Observe, Detect, Identify, and Neutralize (ODIN)—one of the best examples of air-ground ISR integration to come out of the Iraq and Afghanistan wars—was to counter the enemy's IED campaign. Components of the US integrated ISR system included UAVs with FMV and the Liberty King Airs, also equipped with video and SIGINT. In addition to ferreting out IEDs and shortening the decision chain with radio links to Apache helicopters, the ODIN system proved noteworthy for its ability to distribute collected data to common ground stations, cross-cueing human intelligence, imagery, and SIGINT to create "pattern of life" footprints leading to the

4264 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

acquisition of high-value targets and the unraveling of complex IED networks.[10]

One concern with the ODIN network had to do with its performance over the rugged and mountainous terrain of Afghanistan compared with that over the relatively flat landscape of Iraq. A solution to this issue involved the use of airborne communications systems to act as a relay to help integrate air and surface operations. The battlefield airborne communications node was developed to overcome these difficulties by allowing air and ground-based units operating far from each other to see the same ISR picture. The node has been deployed on both manned (the E-11A) and unmanned (Global Hawk) platforms to improve system integration, enhance SA, and strengthen beyond-line-of-sight communications.[11]

What might we conclude from this brief description of ISR platforms, sensors, and their integration employed in counterinsurgency and counterterror operations over the last decade? The demand signal was high, and the targets were time-sensitive, resulting in an emphasis on airborne platforms focused on supporting tactical ground operations in complex irregular warfare. Sensor systems deployed to Iraq and Afghanistan were tailored to a target set of IEDs, moving vehicles, and high-value individuals, driving the need for persistence. C2 of these ISR systems tended to emphasize single communications links between sensor and shooter rather than wideband communications conveying SA to the joint force. Clearly, the innovation in ISR brought to this unconventional battlefield was exemplary, from unmanned reconnaissance-strike systems to nontraditional tactics and techniques. Nevertheless, these platforms could operate only within a sanctuary of uncontested airspace. Had air defenses been more robust, these ISR operations might have proved far more difficult—and certainly less successful.

4265 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Priorities for Twenty-First-Century Defense: Implications for ISR

The shift from counterinsurgency to broader strategic engagement in support of US and allied security has a number of implications for ISR. The document *Sustaining U.S. Global Leadership*, mentioned above, generates these requirements, tilting America's strategic focus and force posture toward the Asia-Pacific. To credibly deter and defend in the future, the policy directs the US military to "invest as required to ensure its ability to operate effectively in anti-access and area denial . . . environments."[12]

These requirements stand in stark contrast to present US ISR capabilities that emphasize counterterror and counterinsurgency operations. ISR will now have to provide persistent coverage over a vast area that could come under attack by adversaries, threatening the operations of US and allied armed forces. The guidance further warns that adversaries in these A2/AD areas will present difficult obstacles to US military intervention. In a follow-on document, the Joint Chiefs of Staff have clarified the ISR requirements dictated by this strategic shift. Specifically, the *Joint Operational Access Concept* charges ISR assets to

- Prepare the operational area in advance to facilitate access. . . .
- Exploit advantages in one or more domains to disrupt or destroy enemy anti-access/area-denial capabilities in others.
- Disrupt enemy reconnaissance and surveillance efforts while protecting friendly efforts. . . .
- Attack enemy antiaccess/area-denial defenses in depth rather than rolling back those defenses from the perimeter.
- Maximize surprise through deception, stealth, and ambiguity to complicate enemy targeting.[13]

It further emphasizes that the "reconnaissance/counterreconnaissance fight is a critical multidomain contest in any combat operation to gain operational access, as each combatant attempts to gain better situa-

4266 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

tional awareness than the other" and that the joint force will demand a major ISR effort applied aggressively. Finally, it notes that this concept will put a heavy burden on continued operations supported by robust C2: "Characterizing an adversary is a continuous activity, commencing years before hostilities begin and continuing during and after those hostilities. This has implications for steady state sizing, systemic capacity, and analytic technologies of intelligence forces. Specifically, the reconnaissance and surveillance contest is critical to access operations."[14]

In an open forum, we can best judge the requirements levied on airborne ISR assets through development of the nascent AirSea Battle operational concept. According to analysis conducted by the Center for Strategic and Budgetary Assessments (CSBA), a "blinding campaign" or "scouting battle" will be the first and most important military move in an A2/AD confrontation.[15] During this phase of the conflict, each side will seek to attack the other's ISR assets and battle networks to deprive the opponent of the ability to detect, identify, and target approaching forces at range. The CSBA study concludes that achieving the technical and procedural interoperability required for a successful joint AirSea Battle will "be toughest with respect to C2, communications, and ISR, simply because these drive the information and data flows" essential to SA.[16]

When the CSBA studies move beyond the A2/AD scenarios in the Western Pacific and the Persian Gulf, pondering the implementation problems inherent in AirSea Battle, they point to the need for rapid and continuing investment in integrated ISR systems.[17] This family of joint ISR systems necessary to underwrite AirSea Battle will have long lead times because of the complexity of integrating various platforms and sensors. Most challenging will be fully compatible and interoperable joint C2, ISR, and processing, exploitation, and dissemination (PED) architectures. Thus, the CSBA concludes that "early Air Force and Navy agreement on efficient migration paths for these architectures is particularly important."[18]

4267 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

ISR in Contested Airspace: Platforms, Sensors, Integration

Two things are clear. First, over the last decade the US military put in place an effective ISR network to prosecute an irregular enemy in relatively uncontested airspace. Second, the United States now needs to replicate that capability in a far more formidable threat environment. In pursuit of this capability, a number of studies are under way that will undoubtedly build on the legacy of effective airborne ISR systems developed and deployed over the last decade. But they are also likely to suggest new approaches in platforms, sensors, and systems to operate effectively in contested airspace.

ISR platforms of the future will need all of the characteristics of those that performed so well over the last decade with one substantial added requirement: survivability in hostile airspace. Although endurance, payload, integration, and connectivity are essential, none of these attributes will be of value if the platform cannot survive in an A2/AD environment. Replacing the Predator and Reaper in the unmanned reconnaissance-strike role will call for new UAVs that can loiter, survive, and attack near and within heavily defended airspace. Most promising here is the unmanned combat air system demonstrator (UCAS-D) undergoing tests by the Navy and the separate but related unmanned carrier-launched airborne surveillance and strike system (UCLASS) program. Whether or not the former is folded into the latter, the unmanned combat aerial vehicle (UCAV) could be designed to carry a suite of sensors and weapons 2,000 nautical miles or more from the carrier without refueling and will have far greater range and persistence if the vehicle can be refueled while airborne. Important to the UAV's survival is its low observability—designed from the start with the stealth to penetrate highly defended airspace. Like its nonstealthy forebears, the UCAV will carry the sensors and weapons to conduct missions of both reconnaissance and precision strike.[19]

4268 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

High-altitude, long-endurance UAVs will also play a role but, depending on the enemy's air order of battle, will have to be operated judiciously and equipped with self-defense capability. Global Hawk and the Navy's Broad Area Maritime Surveillance System, the Triton, might need a self-protection suite that includes a laser warning system, radar warning receiver, electronic attack or jamming system, and a towed decoy. The ISR provided by those high-altitude UAVs can be supplemented by the stealthy Sentinel drone at the tactical level—reportedly a key ISR asset in preparing the battlefield for the raid that killed Osama bin Laden.[20] For the longer term, it may make sense for the Air Force to convert its MQ-X UAV program, now on hold, into a land-based version of the vehicle emerging from the Navy's UCAS-D/UCLASS programs.[21]

The F-22's and F-35's low observability could allow them to conduct nontraditional ISR missions in contested airspace. As the number of jointly operated Joint Strike Fighters increases, they will be able to operate in groups—separated at distances so as not to compromise their stealth but close enough to offer mutual support, such as standoff jamming by one flight of fighters while others penetrate. These stealthy aircraft will have impressive sensor suites characterized as "vacuum cleaners"—collecting data about the enemy's posture and feeding it to joint networks. Meanwhile, the F-35's formidable computational power will allow a real-time recalculation of alternative mission routing in response to intelligence regarding enemy air defenses.

Space-based platforms have been major contributors to collecting ISR data over Iraq and Afghanistan, particularly in cueing other platforms to areas and targets of interest. However, due to the strategic nature of their collection missions and the time that elapses between passes over those areas of interest, satellites have not been considered major players in the pursuit of high-value, mobile, tactical targets. Under new tasking that demands greater wide-area surveillance and strategic assessments over the Western Pacific and Persian Gulf, that perception is likely to change. The increased fidelity of satellite-mounted

4269 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

sensors such as IR and radar, as well as their significant contributions to communications and C2, will likely place greater priority on space-based ISR systems—including the X-37B reusable space plane—in the future.

The systems of targets and the wide-area surveillance needed for the rebalancing of US military forces to the Pacific will also prompt a shift in sensor focus and capability. Each of the platforms described above must tailor its sensing capabilities toward detecting the A2/AD forces and networks (e.g., antisatellite weapons, long-range ISR systems, and precision-guided conventional land-attack and antiship cruise and ballistic missiles) arrayed against the operation of US and allied assets in the region. The ISR capabilities of UAVs will have much to offer, as long as those platforms remain survivable. Thus, a suite of multi-intelligence (INT) sensors, similar to that carried by Reaper and Global Hawk but improved in terms of range and low observability, will allow a new generation of UAVs to make major contributions to SA. For example, advanced sensors with multispectral imaging and multiwave radars might penetrate structures, exposing anything hidden inside. Just as UAV remote sensor requirements stemmed from past changes in military missions, so will new capability requirements arise from emerging military doctrine, including the need for persistence and penetration of advanced air defenses.

UAV payloads might consist of a modular, open-architecture suite of sensors for collecting reconnaissance from across the electromagnetic spectrum and, in the UCAV version, precision munitions capable of exploiting processed information to target enemies with pinpoint accuracy. The requirement for high-definition FMV with its attendant bandwidth, considered so important over the last decade, may take a backseat to large, strategic UAVs with long-range radar, SIGINT, and EO/IR sensors and multifunction radio-frequency-sensor payloads. For example, the Global Hawk Block 40 aircraft with a high-range resolution sensor will allow precision target measurement and classification from high altitude and longer standoff ranges. Similar sensor payloads

4270 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

may let the UCAV find imprecisely located targets on its own, similar to programs such as Tacit Rainbow and the low-cost autonomous attack submunition—abandoned in the past because of uncertainty regarding the unmanned vehicles' reliability for autonomous munitions delivery.

The F-22 and F-35 will also assume ISR roles well beyond the nontraditional role played by fourth-generation fighters with targeting pods over Iraq and Afghanistan. Most notable may be the spherical SA system termed the distributed aperture system developed for the F-35. That system of six EO sensors offers ballistic missile detection and tracking, including launch point detection as well as IR search-and-track functions and day/night navigation. Moreover, both of the fifth-generation stealthy fighters will add ISR capability through their active electronically scanned array (AESA) radars, supplying enhanced target resolution with low probability of intercept and increased resistance to jamming. These aircraft have enhanced defensive sensor suites as well. Just as AESA radar can be used for electronic attack of enemy air defenses, so will the F-35's digital radio-frequency memory capabilities allow the aircraft "to duplicate incoming radar signals, alter them, and send them back to the receiver modified to suggest that the fighter is either not there or is somewhere else."[22]

Given the revived importance of satellites to ISR gathering under the new strategic priorities, space-based sensors must also receive added emphasis. Two capabilities appear particularly significant: space-based radar and IR. The former was an ambitious program initiated a decade ago, designed to provide high-volume, readily available synthetic aperture radar imaging, surface moving-target indications, and high-resolution terrain information to the joint war fighter. Although the program's complexity and cost led to its cancellation, the strategic pivot to A2/AD areas argues for its rebirth. Space radar, which offers coherent change detection to track an enemy order of battle in A2/AD scenarios, has the granularity to detect the launch and track the arc of cruise missiles.

4271 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

A new generation of space-based IR satellites will make major contributions to denied-area ISR. Somewhat ironically, the difficulty experienced by the United States in locating the launch of Scud missiles during the 1991 Iraq war led to an improved capability that now has application in more far-flung theaters of operation. The new space-based IR system, in addition to detecting long-range ballistic missile launches, will contribute to SA of theater missile defense, characterize IR event signatures, and provide intelligence to support force protection, strike planning, and other missions conducted in an A2/AD scenario.[23]

The challenge of integrating ISR assets will become even more complex when military forces operate in A2/AD environments. Over Iraq and Afghanistan, the principal issue involved the quantity of ISR data—a complex system of PED moving vast amounts of data around the theater. In A2/AD airspace, we must pay greater attention not only to the joint and interoperable PED processes but also to their security. One of the approaches both to improving security and handling large amounts of data will entail improvements in the PED process at the multiservice distributed common ground/surface system nodes. A major task at hand involves integrating airborne ISR data into these communications centers. The ultimate architecture must create a network that can fuse and interpret data from multiple sources as well as process and disseminate those data to joint users at just the right time. Particularly important here is an integrated presentation of multisensor, multi-INT inputs on a common joint display.

No matter how streamlined and secure the PED process, however, disseminating ISR data to C2 facilities followed by subsequent tasking to a strike platform imposes unavoidable delays and inserts C2 uncertainties. We learned from operations in Afghanistan that sensor-to-shooter links communicated faster than could be supported by a C2 process requiring evaluation and approval at numerous decision levels. Inadequate communications links, incomplete bomb damage assessment, and poor dynamic airspace management all contributed to

4272 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

shortfalls in the ISR integration process. In uncontested airspace, the Predators and Reapers with FMV and precision-guided weapons filled this gap nicely. Building on that practice, ISR assets in A2/AD environments will need greater airborne persistence as well as sensor-to-sensor integration and data processing at the point of origin to supply real-time information on time-sensitive targets.[24]

A complex mix of platform, sensor, and integration attributes is required to effectively engage time-sensitive or mobile targets in contested airspace. They include range, endurance, survivability, short reaction time, flexible munitions mixes, network connectivity, and onboard mission planning and targeting.[25] Platforms possessing these attributes in varying degrees of effectiveness include the F-22 and F-35 fighters, an armed UCAV (presuming that strike authority is granted with a human in or on the loop), and the B-2 bomber or its advanced technology replacement now under the cloak of security and in development. As autonomous as these platforms and sensors might be, coordinated tactics and engagement profiles in antiaccess environments will demand that stealthy platforms be able to talk to each other. The multifunction advanced data link with high-data-rate, low-probability-of-intercept, and low-probability-of-detection properties is in development for the F-35, but plans to place the link on the B-2 (or the future bomber) and F-22 may have stalled. To integrate these stealthy ISR and strike systems, we must field this data link or something like it.[26]

Just as space-based sensors and platforms will prove critical to ISR in A2/AD scenarios, so will space-based communications prove essential to ISR integration. Replenishment of the Global Positioning System, now under way, is needed for the timing and positioning of ISR assets and required for the guidance of air-launched precision weapons. The jam-resistant and nuclear-hardened Milstar communication satellite constellation is being replaced by the advanced extremely high frequency (AEHF) satellite system, which will provide enhanced capacity and clarity-enabling ISR asset integration at both the strategic and tactical levels. The next generation of satellite terminals, known as the

4273 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Family of Advanced Beyond-Line-of-Sight Terminals, is also necessary to facilitate communications between airborne ISR assets and AEHF satellites.[27] We can also protect satellite communication by restarting the laser-based transformational satellite system, once abandoned but now strengthened by a broadened industrial base and mature technology readiness.[28] Finally, self-defense will also be necessary for space-based assets in A2/AD scenarios.[29]

Conclusion

In directing a strategic shift away from a decade's emphasis on large-scale counterterror, counterinsurgency, and prolonged stability operations, the nation's defense leaders have issued a powerful challenge to the airborne ISR enterprise. Because of the uncontested environment for the operation of an ISR family of systems over Iraq and Afghanistan, the platforms, supporting sensors, and C2 connections cannot simply be lifted and relocated to a new theater of operations. Nevertheless, the joint force can still profit from years of effort in establishing tactics, techniques, and procedures that replaced the ponderous practice of transferring actionable intelligence to the operator, which so often had the counterproductive effect of disrupting the relationship among sensor, decider, and shooter.

Force planners with an airborne ISR portfolio can also profit from the joint "family of systems" approach adopted by their colleagues who deliberate future platforms, sensors, and integration for long-range strike.[30] As comparisons are drawn across different scenarios, the worth of these individual systems varies markedly. Penetrating deeply into defended territory, surveilling targets from long range, loitering and tracking time-sensitive targets, and surviving in defended airspace with integrated ISR and strike capabilities can all lead to differing solutions. Given this range of requirements, a family-of-systems approach that offers diverse ISR platforms, sensors, and integration options appears prudent in a security environment populated by emerging ad-

4274 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

versaries who present differing antiaccess challenges. But this family of systems must be connected across the armed services.

More work remains, and several studies exploring ISR in contested airspace are under way. Lessons identified from recent wars continue to stress the power of ISR integration for effective C2 while the challenges of operating in contested airspace will place a premium on varying approaches to survivability. In any scenario, the issue of ISR in A2/AD environments will involve getting the right information to the right person at the right time to make the right decision. We should use studies and war games to adapt the effective ISR network put in place over the last decade to more stressful conditions, and we should identify the investments needed, particularly when a long lead time is necessary to gain a desired ISR capability. To ensure that the prowess so ably demonstrated by airborne ISR systems in uncontested airspace does not atrophy in the face of increasingly nonpermissive environments, we must accelerate those studies and provide the needed investment. ✪

Machine Autonomy in Air-to-Air Combat

Capt Michael W. Byrnes, USAF*

Although one finds no shortage of professional and academic conversation about remotely piloted aircraft (RPA) and potential unmanned combat aerial vehicles (UCAV), there is a distinct lack of forecasting of their futures on the basis of a tight fusion of tactics, technology, and the enduring truths of air combat. This article claims that a tactically autonomous, machine-piloted aircraft whose

design capitalizes on John Boyd's observe, orient, decide, act (OODA) loop and energy-maneuverability constructs will bring new and unmatched lethality to air-to-air combat. It submits that the machine's combined advantages applied to the nature of the tasks would make the idea of human-inhabited platforms that challenge it resemble the mismatch depicted in *The Charge of the Light Brigade*. A convergence of new technologies indicates the earliest stages of emergence of a tactically game-changing approach to air warfare, but the institutional Air Force appears skeptical—perhaps since this theory of air dominance begins life in an environment resistant and rightfully cautious toward its development.[1] To date, a credible RPA optimized for air combat has not been developed, and the nation and service face severe fiscal austerity, increasing risk aversion.[2] Furthermore, the idea of a machine outflying the world's best fighter pilots may frustrate and unsettle conventional wisdom, inviting political contention.

However, if logic proves the dominance of this theory of machine autonomy in airpower and if the technology to execute it emerges, then making the emotional decision to reject it places our forces at strategic risk. To show that such claims are reasonable, the article presents a notional UCAV termed *FQ-X* to provide a guided tour through emerging real-world technologies and to show their tactical implications in an engagement. The discussion shifts to assessing briefly how these tactical effects ripple into the operational and strategic and then closely examines autonomous decision making in the context of the OODA loop before taking a deep dive into the technologies behind machine pilotage. Finally, the article counters prominent objections to the machine pilot in the arenas of cyber defensibility and the ethics of killing by a proxy weapon capable of making its own decisions. It wraps up with an assessment of the tactical and cultural integration challenges that lie ahead for the Air Force at the appearance of these novel systems.

4279 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

FQ-X Design and Features

The form of a machine like FQ-X, whose purpose is to find and destroy enemy aircraft, will favor small size and weight, great speed, low detectability, and unprecedented accuracy. The design exploits cutting-edge metamaterials that complement radar-absorptive materials to generate specific tactical advantages. Metamaterials are synthetic structures that demonstrate effects previously thought physically impossible. Specifically, negative-index-of-refraction metamaterials are capable of refracting electromagnetic energy in a way that "bends" it around (rather than bounces it off) an object, rendering it invisible in a particular region of the spectrum. Researchers proved techniques to do so as early as 2001 and less than 10 years later in the visual and infrared spectra.[3] By 2012 a team had even devised methods to overcome geometry and polarization limits, which were showstoppers for the use of metamaterials to hide a large object like an aircraft.[4] The implication for airpower is that a new generation of extremely stealthy materials is emerging, and the military does not have the luxury of keeping them a secret. Their utility in a variety of civil and military applications may also lead to their relatively cheap and plentiful manufacture. Although no stealth technique is flawless, metamaterial layers within a dielectric composite skin of FQ-X severely hamper current detection and identification methods. Preventing an enemy missile lock on an FQ-X is an excellent return on investment, but the overriding reason for stealth is that FQ-X focuses religiously on the OODA loop. The priorities are to defeat the operator's decision cycle first and missile-guidance systems second. When the aircraft is successful at both, it sidesteps a staple of modern air combat, undermining a multibillion-dollar national security investment.[5] When a scenario does not permit slipping past the allowable weapons-employment zone of air-to-air missiles, existing countermeasures and emerging directed-energy point defenses are excellent options for an aircraft with millisecond reaction times.[6]

4280 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Defensive capabilities are of limited value if not paired with tools to find, fix, identify, and target hostile aircraft. Radar technology has evolved to the point that superficial assumptions about its capabilities are no longer accurate. For example, it would be natural to think that if a transmitting aircraft sends out a pulse of energy to detect an opponent, then that opponent (who was just hit with that energy) should be able to notice and respond. However, modern radars with low-probability-of-intercept technologies transmit at power levels below the receiving aircraft's detection threshold, working across multiple frequencies and across time to integrate the collection of weaker returns into a coherent signal.[7] Modulation techniques applied to active electronically-scanned-array antennas allow for multiple beams, which translates to multiple target acquisition and engagement.[8] The key to all of these fantastic capabilities is the capacity for digital signal processing.[9] The principle of "first look, first kill" belongs to the aircraft with the most processing power and the best software to leverage it. F-22 processing power is on the order of 5 billion decimal operations per second.[10] Modern graphics processing units can execute digital signal processing for radar applications at 10 to 100 times that speed and are available as affordable commercial off-the-shelf hardware.[11] FQ-X uses arrays of graphics processing units to showcase how much the "find and fix" stage of air combat is really a battle for computing power, which it leverages from general-purpose hardware, shifting task specialization into software to reduce cost and increase flexibility.

Today's predominant use of guided missiles is already an implicit admission of reliance on automation, and if the machine pilot can outperform human processing in the most allegedly artistic piece of air combat, simpler ones also likely favor the machine. To demonstrate, FQ-X collapses to gun range to outmaneuver the modern human-inhabited fighter, exploiting both positive and negative G choices. FQ-X's options are flexible, thanks to carbon nanotube composite structures and the absence of a human inside. Carbon nanotubes are microscopic structures formed in 1952 lab experiments that did not reach broad awareness in the Western scientific community until 1991.[12] In 2012 re-

4281 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

searchers at North Carolina State University demonstrated fabrication of large-scale carbon nanotube materials that showed a remarkable 30 percent improvement in specific strength over the world's best-engineered composites.[13]

Once positioned to attack, FQ-X needs to deliver hyperprecise effects to maximize use of a comparatively lean arsenal that a small craft is likely to contain. To that end, it has a nearly all-aspect targeting system accurate enough to pick a particular spot on an opposing aircraft to place a high-explosive round or directed-energy burst. To positively identify the target and hit the desired spot, FQ-X must have integrated multispectral optics and computer vision software. One of the largest commercial drivers of this object detection software is Google (which pursues the technology for image-based search engines).[14] However, open-source projects like OpenCV, containing more than 2,500 optimized detection and recognition algorithms, are also rapidly advancing application of the science.[15] Computer vision frameworks such as OpenCV also take advantage of graphics processing units to speed processing functions five to 100 times faster than traditional computer hardware.[16] Figure 1 depicts an engagement approaching this endgame state from FQ-X's computer vision perspective, first from a notional US system's display and then from a hypothetical competing foreign version.

4283 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

With clearance to engage, it fires an armor-piercing high-explosive incendiary round into a critical system like the first compressor stage of an engine, rapidly ending the engagement with little opportunity for the adversary to adapt. FQ-X, on the other hand, learns from every detail of the encounter with real-time machine learning. It can pass lessons to other UCAVs, making partnered aircraft smarter by every engagement. Besides direct aircraft-to-aircraft sharing, the FQ-X air vehicle can send its telemetry to a ground control station (GCS). In the event an air vehicle is destroyed, its last moments may be stored on a secure network via the GCS. The implication may not seem obvious at first, but contrasted to the loss of a human-inhabited fighter, the difference is staggering. Losing a human pilot is a tragedy, and in cold but factual terms that a commander must face, it means the loss of an enormous investment of time and money in training and operational experience. If a veteran pilot falls in combat, then a young rookie has to take his or her place, starting a cycle of development all over again. The machine pilot, however, learns from death and in near real time commits adaptations to other UCAVs in the fight. Opponents may find that the same tactic never works twice against these systems.

Implications: Ripping into the Operational and Strategic

If machine-controlled maneuvering and accuracy make every cannon round a "golden BB," then left unchecked a single FQ-X with a few hundred rounds of ammunition and sufficient fuel reserves is enough to wipe out an entire fleet.[17] The economics of this approach are similarly stunning to consider and require examination with a global airpower perspective. The Russian-Indian jointly developed FGFA (PAK-FA derivative) is still several years from reaching initial operational capability and seems subject to the same delays and cost spirals of any highly complex development program.[18] Conservatively, current estimates are about $100 million per copy and likely to rise.[19] On the US side of the equation, each Raptor has a flyaway cost of $148 million, each F-35 in low-rate initial production was $153 million during 2011,

4284 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

and a fighter pilot costs an estimated $2.6 million.[20] An AIM-9X missile is approximately $300,000.[21] If the aircraft and crew are fixed setup costs and their weapons are marginal costs of engaging a target, then the FQ-X system is poised to become substantially more affordable than the fifth-generation fighters it is engineered to overcome. FQ-X has a high percentage of commercial off-the-shelf hardware, small size, and no need for a one-to-one crew-to-aircraft ratio. The marginal cost for two stabilized cannon rounds fired at close range is a mere $20.[22] A rechargeable directed-energy weapon's cost to employ would depend on maintenance required per 100 firing cycles but would be inexpensive in a mature design.

Any compromise of defensive counterair ability jeopardizes high-value airborne assets, tanker and mobility aircraft, and the Airmen aboard them, opening the possibility for losses on a scale that our own service has not endured since its bombers attempted daylight raids in the 1940s.[23] The difference between then and now, of course, is that our industrial production base and budget are not configured to replenish such high attrition. In our efforts to become an effects-based force, we redefined mass by concentrating more capabilities in fewer physical assets, and that strategic choice has trade-offs.[24] Europe, Russia, India, and China have followed us into the game of big, high-tech fighter projects as well, thus framing a global problem-solving mind-set about how nations build airpower.[25] With so much depending on the current paradigm, an aggressor FQ-X performing as advertised in a US Air Force Weapons School event would become an inflection point in airpower history. Assuming that sixth-generation systems will simply be refinements of their fifth-generation predecessors falls well short of positively revolutionizing lethality, economy, and capability of airpower, and it invites increased risk to our current assets.[26] The path forward to continued assurance of air dominance starts by redefining our most basic understanding of what an airplane is and continues by applying well-established truths about air combat to new technological opportunities.

4285 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Flying Machines: Heart of the OODA Loop

Aviators instinctively see the airplane as a machine whose purpose is to fly rather than a machine that flies to serve its purpose.[27] However, if the Boyd cycle lies at the heart of describing success in air combat, then it makes sense to give priority to the elements of an aircraft most responsible for supporting speed and accuracy in the OODA loop and call all others secondary. RPAs and UCAVs are computers with airframes strapped to them, not the other way around. Flight-control actuators, avionics, radios, sensors, and even weapons are like plug-and-play peripherals for this platform, just as one might plug in printers, scanners, or cameras to a personal computer. This view reveals an opportunity to affect the flexibility and affordability of sixth-generation airpower. Decades ago, open architecture of IBM PC clones enabled massive proliferation of computing technology.[28] Similarly, pursuing plug-and-play standards, commercial off-the-shelf hardware, and common operating systems for autonomous aircraft and their GCSs supports proliferation and cost reduction that help to accelerate the pace of research, development, testing, and operational use. A tactically autonomous aircraft like FQ-X need not seek science-fiction-like self-awareness; within the scope of air-to-air combat, it is an airborne computer that executes the underlying mathematical truths of what human combat pilots do in the cockpit, doing so more quickly and with more precision.

Boyd's OODA loop implicitly reveals that the "art of flying" is actually a cyclical processing activity. It includes sensory data acquisition, reconciliation against known information to derive meaning, selection of a response from a known repository of possible choices or synthesis of a new option when none is satisfactory, and execution of the choice. Machine-learning algorithms address these tasks in two modes: supervised (designers train the software by telling it right from wrong) and unsupervised (it determines if a new action is right or wrong by experimentation and by extension of what it already knows).[29] A machine pilot with appropriate sensors and multiple computing cores can ac-

4286 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

quire and integrate information from diverse sources more quickly and reliably than a human.[30] With a trained artificial intelligence (AI), it can also draw clearer interpretation from data without human psychological biases. Humans average 200–300 milliseconds to react to simple stimuli, but machines can select or synthesize and execute maneuvers, making millions of corrections in that same quarter of a second.[31] Every step in OODA that we can do, they will do better. Although Boyd's hypothesis is a cornerstone of fighter aviation, an inadvertent consequence of its logic in this evolving context is that machines will inevitably outfly human pilots. Furthermore, machine pilots do not have continuation-training requirements or currencies to maintain.[32] Unlike humans, whose skills regress without reinforcement, tactically autonomous aircraft can "sit on a shelf" for extended periods of time and remain exactly as sharp as they were the day they were pulled from service. Budget sequestration grounded 17 squadrons and did long-term damage to combat readiness—an effect that autonomous airpower would not suffer from. That $591 million cut represents an overhead cost which simply would never have existed in the first place with machine pilots.[33]

Tactical Autonomy Today

A common objection to this application of the OODA loop claims that the machine will not be able to do one or more of these tasks at the same level as human cognition, particularly the "orient" and "decide" steps. One author concludes that "the information required to make such a decision [to fire weapons] comes from so many sources and could be so easily spoofed or jammed by the enemy, that the validity of that computerized decision could never be fully trusted."[34] Unfortunately, he presents no discussion of the specific technical challenges and solutions, instead generalizing to conclude that "what separates men from machines is the ability to see opportunity and use it creatively."[35] In fairness, that author's point was not "anti-unmanned aerial vehicle (UAV)" but a wise call for caution about how much faith

4287 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

we put in these yet immature aircraft. Still, reconciling his perspective against recent technical developments reveals that his viewpoint does not anticipate the direction in which machine pilotage is evolving.

In 2012 the Defense Science Board released a study on the role of autonomy in Department of Defense systems, finding significant opportunity for RPAs to further leverage existing computer vision, AI, and machine-learning technologies to add value through onboard autonomy.[36] To get a sense of how underexploited existing AI really is, consider that in 2008 an MIT researcher (and former F-15C pilot) successfully executed machine-learned, real-time, basic fighter maneuvering using a neurodynamic programming technique in a flight-test lab.[37] The software adapted rapidly and learned to maneuver into a weapons-employment zone by discovery rather than by being taught exemplar tactics (fig. 2). The MIT work shows that the basis for autonomous unmanned fighters exists in building blocks and that future maturation would add sophistication to take the technology beyond the lab and into complex flight environments.[38] In another compelling development that would facilitate machine pilotage, researchers in the AI subdiscipline of neuroinformatics recently constructed "neuromorphic" chips that behave like synthetic neurons on silicon substrate, imitating brain function and allowing incorporation of complex cognitive abilities in electronic systems.[39] A University of Zurich team presented a design capable of performing complex sensorimotor tasks that, in an organic brain, require short-term memory and context-dependent decision making.[40]

4288 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

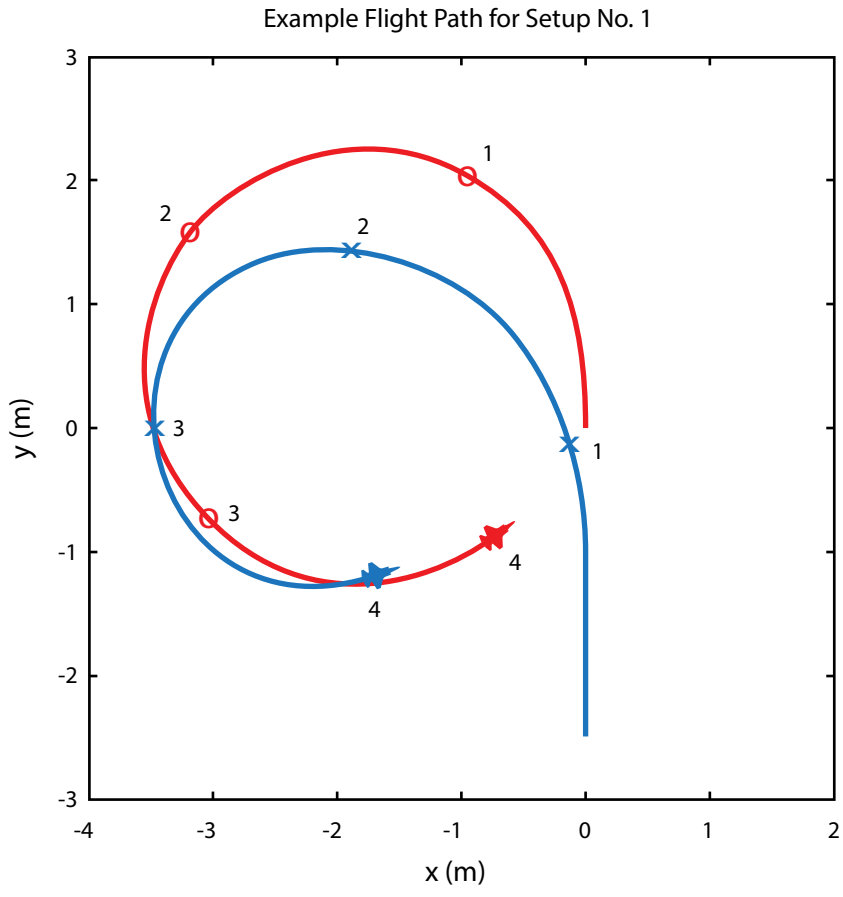

Figure 2. UAVs learning basic fighter maneuvering from a perch setup. (Adapted from James S. McGrew et al., "Air-Combat Strategy Using Approximate Dynamic Programming," *Journal of Guidance, Control, and Dynamics* 33, no. 5 [September–October 2010]: 649. Reprinted with permission from James S. McGrew.)

An applied information technology perspective and increasingly evolved AI technologies suggest that new UAVs will thrive when granted tactical autonomy. These machines cause us to revisit the notion of "centralized control, decentralized execution." This codified Air Corps doctrine, born in a world without real-time video feeds, taught that commanders of an air campaign had to grant crews a high degree of autonomy, entrusting them to accomplish a mission.[41] Later, real-time connectivity to the cockpit (or a GCS in control of a remote air-

4289 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

craft) allowed commanders to be as tactically hands-on or -off as they saw fit.[42] With FQ-X, autonomy for the conduct of the engagement would return to the air vehicle to take advantage of its superior processing speed and reaction times. The Defense Science Board study, however, points out that a machine's autonomy to perform tasks does not preclude its adherence to rules of engagement or suggest that it is totally absent of human supervision.[43] Human decision making at a higher level is crucial to bridge the tactical to the operational, but these machine-pilotage technologies suggest that stick-and-rudder skills might not be an Airman's central value proposition.

Hacking the Mission

Reliability of the machine pilot is a natural concern. Potential defects in the design are more likely than computer hacking and are most effectively abated through comprehensive testing demanded by the best practices of software engineering. The fear of cyber attack relies on the belief that any computer system can be hacked.[44] A more accurate answer, however, is that breaching the security of an information technology system *requires the defender of that system to make a mistake in design or operation*. In highly complex systems, that fact leads to a cycle of vulnerability discovery, analysis, and repair or mitigation. It is therefore critically important to engage in thorough testing and security reviews at every step of the system's design and to keep the authorized user's opportunities to commit an unsafe act to a minimum through excellent design of human-computer interaction.[45] All "cyber" attacks are attempts to negatively affect the confidentiality, integrity, or availability of a system.[46] Like their counterparts in the kinetic realm, they are observable, repeatable tactical actions that one can study and counteract.

The intersection of classically kinetic air combat and more novel cyber activities paints a fascinating picture of the potential employment methodologies and skill sets demanded of crews that operate assets like FQ-X. From a cyber-defense perspective, for example, shooting

4290 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

down the air vehicle falls under the category of a physically based attack against system availability.[47] A fighter pilot would simply say, "You lost and got shot down," analyze the tactical reasons in a debriefing, and teach how to win next time. Both perspectives are simultaneously valid, and both mind-sets extend from common points of overlap in different directions: one toward a very kinetic, visceral, tactical set of problem-solving skills, and the other toward analytically preventing exploitation of a computer system. A design like FQ-X is subject to the rules of both worlds and needs those employing it to operate in a unified framework that addresses both air combat and cyber-defense concerns. The cyber defender is unlikely to be able to look at an air battle and integrate tactical- and operational-level concerns to prosecute a war. The fighter pilot is unlikely to be able to detect and counter an enemy's attempt to launch a complex exploit against the UCAV's operational flight program. The good news for the US Air Force is that it has a rich heritage of expertise at all levels of air warfare and is actively developing capability in the cyber realm.[48]

Ethics of Autonomy

As frequently as skeptics cite hacking as a potential weakness of unmanned flight, consideration of the ethics of autonomous weapons employment captures far more public apprehension. The discussion sits amidst a much larger and more ambiguous debate about remote and robotically enabled warfare. A search on Amazon for "drone warfare" books revealed nearly 30 promising titles and almost 200 total results. A Google Scholar search for the same topic returned 14,800 results. A third of the *Routledge Handbook of Ethics and War* is dedicated to drone and cyber topics, and the entire cover image depicts an armed MQ-1B.[49] *Jus in bello* (the justice of conduct in war) arguments regarding the use of RPAs focus much of their contention on targeting criteria, collateral damage, and debates about the wisdom of overreliance on military instruments of power. Those issues are important national discussions, but to cut through the noise of so many conversa-

4291 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

tions and emphasize the ethics of truly tactically autonomous combat calls for a scholarly work like Armin Krishnan's *Killer Robots*.[50]

Krishnan clearly delineates between the types of robotic systems involved in the military's trade, and the FQ-X concept intersects his definitions of the terms *unmanned aerial vehicle* and *autonomous weapon*.[51] He raises the concern that once an advanced machine demonstrates capability and offers the economy of not having to pay health care or retirement benefits, the military and its political masters will become fixated on the efficiency and convenience of replacing humans on the battlefield. If they do so, perhaps also seeking the political convenience of minimizing casualties, they will fail to consider the qualitative, long-term consequences of that choice.[52] The irony of a pure, unbridled quest for combat efficiency, as political-military strategist Thomas K. Adams points out, is that sooner or later the inventors realize that humans are always the weakest link in a system. They optimize human operators and then human decision makers out of the equation to replace them with another machine. As an argument to the extreme, he suggests that the cycle repeats until the tactical level of war involves no humans at all, rendering the whole activity a pointless waste of resources that fails to resolve the human needs that triggered it in the first place.[53] A government must respect the ethics of its civilization and consider what statecraft and warfare communicate to the world about its people. In the case of FQ-X, the most pressing question concerns whom to hold responsible for the conduct of a proxy weapon that makes its own decisions.

If the device functions as intended, the ethics are simple: the UCAV is an extension of the will of the person who commanded it, and the chain of responsibility traces from the operator up the kill chain of the command and control structure. If, however, the system deviates and kills people the operator never intended to harm, then assignment of blame becomes more complicated, calling into question the degree of autonomy one can grant a machine and how much human supervision must remain in the kill chain.[54] The Air Force encountered a parallel

4292 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

situation in which a complex system broke down during the 1994 Blackhawk incident. Skilled Airmen working across multiple platforms to control airspace utterly failed, and 26 people died unnecessarily as a result. That system was defined by people, policies, practices, training, technologies, and rules of engagement. In the end, not one person went to jail because of the incident.[55] Systems like FQ-X will similarly employ procedural guidance to reflect a combatant commander's intent, though translated into a digital form subject to error checking and closer scrutiny. Regardless of analog or digital means, however, an enduring takeaway of the Blackhawk incident appears to be that attaining the satisfaction of justice becomes difficult when responsibility is diffused in complex systems. We must deliberately plan how to take responsibility for the things we intend to create; otherwise, we will have no more satisfying answers than we did in 1994—or in any friendly-fire or civilian-casualty event before or since.

Ethical debates guide the implementation of any new means of war fighting, making a technology either admired or monstrous before the court of public opinion. Autonomous weapons must reconcile a tactical desire to exploit the benefits of their independence—for example, reducing signatures by disabling data links during an engagement—with our moral need to limit the diffusion of responsibility to nonhuman actors in a system. One solution is to break the autonomous air-to-air engagement into five phases—searching, stalking, closure, capture, and kill—and then assign discrete levels of autonomy and operator interaction per phase.[56] This approach would allow the UCAV to maximize its time under autonomous, low-detectability conditions and reach back to its human operator at key junctures where moral questions trump the tactical risk. Another method would authorize firing freely on enemy unmanned systems but require operator consent to take a human life. Such techniques are merely extensions of existing methods of managing lethal autonomy.[57] Joint terminal attack controllers call for close air support in one of three types, and each type allows the pilot (a semiautonomous entity to the controller on the ground) different degrees of freedom.[58] Just as air forces build the

4293 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

ground component's trust in airpower, so must UCAV designers progressively prove new systems—as one author suggested might be appropriate in pursuit of an optionally manned design for the Air Force's next long-range bomber.[59] This line of thinking is consistent with the Defense Science Board's study on the role of machine autonomy.[60]

Integration and Cultural Issues

Air forces that have an ecosystem of aircraft specialized in distinct tasks succeed over those with aircraft designs burdened by divergent workloads. L'Armée de l'Air learned that lesson disastrously at the hands of the Luftwaffe in 1940.[61] Systems with the capacity for tactical autonomy, like FQ-X, will not go to war alone and will need to integrate their capabilities with dissimilar UAVs and human-inhabited vehicles. Autonomous aerial refueling, for example, may manifest from follow-on work after the Defense Advanced Research Projects Agency's KQ-X project or the Navy's unmanned combat air system demonstrator.[62] If so, KC-46 acquisition just beginning in the midst of UAV advances suggests a long period of overlap with both manned and unmanned platforms providing global reach. The exact pattern of integration—which assets will be autonomous, remotely piloted, or human inhabited—will have as much to do with availability of assets that can do the job as with the combatant commander's vision, preferences, and comfort level. Certainly, a strong need will exist for deep, pervasive integration across all available air assets in order to maximize the utility of every platform in the ecosystem of an air force.

Recent discussion of how to fit future autonomous and remotely piloted systems into an air order of battle and into the cultural fabric of the service has been lively in *Air and Space Power Journal*. The prevailing theme is that semiautonomous UCAVs will serve as wingmen while the manned fighter remains the centerpiece of air warfare. The most disturbing thing about this notion is that it attempts to serve two masters: avoiding saying anything upsetting while also trying to advance the development of UAVs. It is also strictly "forward pass" think-

4294 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

ing, as if chair-flying an ideal sortie without simulating enemy responses in a "backward pass" through the concept.[63] Its assumptions are that (1) force multiplication is all we require of UAVs and (2) in air combat, none of these platforms can defeat manned fighters directly. One author even states that they "will not replace the manned fighter aircraft—we cannot build a control system to replicate the sensing and processing ability of trained aircrews."[64] That article offers neither technical nor research data to qualify its indefinite, unrestricted claim. In light of the research evidence in favor of machine pilotage, that statement is suspect.

In another article from the same release of the *Journal*, Maj David Blair and Capt Nick Helms suggest that manned-remote fusion represents the future of airpower and argue that the principal hindrance to realization of that future lies within Air Force culture rather than technology.[65] Their analysis seeks to reconcile the roles of these two breeds of airpower and their accommodation within the Air Force's operational culture. However, it also envisions the fusion of manned assets and UAVs whereby human-inhabited assets unquestioningly lead the fight into contested airspace. It never stops to ask whether the application of Boyd's words to this emerging technology would actually render such a future improbable. As a competing construct, FQ-X pushes OODA to nanosecond resolution and argues that the air-to-air decision-making cycle of a human pilot, at its best, could never logically win a direct contest with pure machine autonomy—meaning that competition for primacy does in fact exist.

Still, they believe that

> the true conversation does not deal with competition between humans and machines. Instead, it concerns the nature of cooperation between them. . . .
>
> . . . The fear that pilots are replaceable is best answered by using the lens of technology to amplify the things truly irreplaceable about them. Technology then ceases to be a threat, allowing us to magnify our distinctively human capacities of judgment, reasoning, and situational awareness across the battlespace.[66]

4295 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

These authors seek the inclusion of RPA operators into the larger fold of pilots, emphasizing the Air Force's chosen *RPA* term, to demonstrate that pilotage is more than sitting in the cockpit.[67] Conversely, thinkers such as Houston Cantwell recommend dropping the pilot terminology, along with the stick and rudder, to allow these aircraft to come into their own and realize a potential separate and distinct from that of manned aircraft.[68] He also exposes a hurdle to Blair and Helms's seemingly reasonable approach in that many pilots have wrapped their personal identities so tightly around the act of flying that they will not give it up if asked politely. In fact, one-third surveyed would rather leave the service than fly RPAs.[69] Cantwell, Blair, and Helms would all agree, however, that a concentration on inputs (the stick and rudder) rather than outputs (combat effects) reflects twentieth-century thinking that will not advance airpower.[70]

Regardless of the terminology or approach selected, these cultural issues drive organizational priorities that affect how, when, and even if the Air Force chooses to invest in autonomous technologies. Research on organizational core competencies published in the *McKinsey Quarterly* reveals that "the company's power structure cannot be driven by several functions at once. . . . A world-class competence must steer the power structure in a company. The keeper of the skill drives all the company's major decisions, even in unrelated functions."[71] Although the Air Force espouses three core competencies that enable six distinctive capabilities, in practice it cannot escape the interplay of core competency and power structure.[72] The apparent skill driver in the Air Force is the successful execution of air-to-air combat. Recent commentary from Lawrence Spinetta highlights that leaders in the fighter enterprise have the opportunity to command at 26 wings whereas the RPA enterprise has only one.[73] His interest in the discussion is not about emotive perceptions of fairness; rather, it hangs on Stephen Rosen's observation that the pace of innovation in the military is restricted by the speed at which officers (who, in retrospect, possessed the innovation) rise to consequential levels of the command structure.[74] The concern articulated by Spinetta is that hanging on to fight-

4296 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

ers so tightly as to slight RPAs (or UCAVs) discards opportunities to preserve the nation's technological edge. Choosing not to respond to FQ-X on the basis of perpetuating the service's power structure could actually nullify the value that structure delivers.

Conclusions

The technological landscape is replete with advances heralding profound change for the means of success in air combat. Nevertheless, certain long-standing discoveries about the nature of airpower itself endure—namely, Boyd's OODA loop and the value of an aircraft's autonomy, whether or not a human is physically aboard. Hyperstealthy metamaterials, carbon nanotube composites, sophisticated computer vision, and advanced AI work in concert to open the door to a new generation of aircraft. These technologies can improve the survivability of human-inhabited vehicles, but combined application in a tactically autonomous system is key to unlocking new levels of performance and economy in air combat. Consideration of cyber and ethical dimensions remains a responsibility of exploring this new potential. Integration with other assets and primacy in the battlespace will prove contentious, particularly since today's RPAs exhibit such constrained performance; however, the notion that all such aircraft will be mere force multipliers for manned fighters represents a potentially tragic underestimation of the capability, efficiency, and lethality of machine pilotage. Functional and subsequent political displacement of the fighter pilot may be an emotionally charged idea, but our developmental priorities must reflect the need to preserve our Airmen, fleet, and sovereignty. Being second to market with tactically autonomous UAVs adds risk. Whether the technology reaches viability next year or in 30 years, its present-day versions prompt us to analyze the logic of their potential. If the machine pilot can usurp the organic one's most prized art form, then that ability raises the question of why any nation would seek a human-inhabited sixth-generation fighter—even if both options were similarly priced.

4297 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Aviators may dislike it, the public will question it, science fiction imagines harbingers of the Cylon apocalypse, and we are uncertain about how to best utilize it within the context of a larger Air Force.[75] Nevertheless, the FQ-X concept is too dangerous to our current thinking to ignore forever. The standard rules of the arms race apply: if a rival succeeds first, then our failure would be judged by the words of our own airpower theorists. Just as air superiority is a prerequisite for combined-arms victory, so will tactically autonomous UCAVs (or a novel measure to counter them) become a prerequisite for the survival of fleets of human-inhabited air vehicles. In a technology-dependent service, the cycle of invention, skepticism, resistance, and adaptation continues—all of this has happened before, and all of it will happen again. This particular time, however, it may not matter how undesirable the Air Force culture finds it. Key enabling technologies are evolving outside the military's control. Much of the maturation of unmanned systems occurs with commercial capital to meet civilian business objectives across multiple industries.[76] Creating legal controls is precarious for dual-use technologies that serve principally civil purposes and simultaneously underpin devastating capabilities like FQ-X. Common technical standards obscure the line, and increased computing power raises the stakes for what these systems can accomplish. Ubiquitous dual-use, however, is an opportunity for cost reduction in the development of these aircraft.

Deliberately ignoring tactical machine autonomy may do little to slow its arrival, and for the Air Force, the most proximate threat to resistance may not come from foreign entities but from within the joint team. The US Navy, whose institutional future is tied to its ships rather than what flies off their decks, has outshined its sister services in advancing UAV technology. Common GCS designs, X-47B, and recently opened competition for the unmanned carrier-launched air surveillance and strike system (that awarded four $15 million contracts) show that the Navy is incrementally maturing the technology and concepts.[77] That service will soon have far more impressive UAVs than the Air Force. We might find ourselves right back in the days of acquiesc-

ing to the purchase and rebranding of a Navy plane, as with the F-4.[78] ✪

Notes

1. Air Combat Command's (ACC) strategic plan for 2012 omits the terms *UAV*, *UCAV*, *RPA*, or *unmanned* and includes only a single picture of an RQ-4 amidst a collage of other aircraft. Whatever the long-term intent, exclusion in the document reveals that this enterprise is not a first-order priority although the plan clearly states that ACC maintains lead integration responsibilities for global intelligence, surveillance, and reconnaissance and actively seeks to invest in recapitalization, a "Next-Gen fighter," and "a holistic set of game-changing capabilities and cross-cutting technologies" (12). The overall impression communicated is that ACC desires new technology, but it does not convey that remotely piloted systems represent the kind it seeks to develop. Air Combat Command, *2012 Air Combat Command Strategic Plan: Securing the High Ground* (Joint Base Langley–Eustis, VA: Air Combat Command, 2012), especially 3–15, http://www.acc.af.mil/shared/media/document/afd-120319-025.pdf.

2. The Air Force armed the RQ-1 with an AIM-92 Stinger missile in 2002 and fired on an Iraqi MiG that crossed into the no-fly zone but did not win the engagement. Allegedly, a guidance error within the missile prevented it from hitting the MiG. 17. The kind of gun targeting system proposed herein would represent the most difficult design challenge after the core artificial intelligence (AI), and it would represent the highest risk item to project success. If the AI fails to meet expectations, the technology might still be transferrable for other less-challenging projects. However, if high-resolution air-to-air gun targeting proves too difficult a problem to solve, then the entire asset must be redesigned to accommodate a different operational construct (e.g., small short-range missiles or a return to conventional radar-guided missiles already in inventory), which may still offer value or may diminish the value proposition substantially. Lessons learned from the software-engineering industry suggest tackling the highest-risk segments of software-intensive systems first through controlled experiments rather than launching into a project via the easiest tasks and later becoming stuck at a point where costs and pressure on the industry team begin to mount. 30. This article restricts the discussion to air-to-air applications because they present an extremely sterile environment compared to the air-to-ground (surface attack) domain. Acquiring and processing sensor data against a relatively empty background are far simpler than doing so against a cluttered backdrop of Earth's surface and all of the natural and man-made objects layered upon it. Surface attack is also extremely context dependent whereas air-to-air combat follows a more streamlined set of rules regarding electronic and visual identification measures and reconciliation against published rules of engagement. correspondence, 18 August 2013. Captain Wilson predicts that the Air Force, strained by severe budget limitations and frustrated in its attempts to innovate amidst high operations tempo, will likely accept the US Navy's lead on RPAs in the short term.

Capt Michael W. Byrnes, USAF

Captain Byrnes (USAFA; MS, Carnegie Mellon University) recently arrived at the 29th Attack Squadron, Holloman AFB, New Mexico, to serve as an MQ-9 Formal Training Unit instructor pilot. Previously, he was a dual-qualified MQ-1B pilot and an MQ-9 instructor pilot working in the weapons and tactics section of his last squadron at Creech AFB, Nevada. He has flown more than 2,000 hours of diverse mission sets in the MQ-1 and MQ-9 in support of worldwide contingency operations. A graduate of the Euro-NATO Joint Jet Pilot Training Program and a distinguished graduate of the Air Force Academy, Captain Byrnes served as an enlisted avionics-sensor-maintenance journeyman prior to commissioning.

"Finnishing" the Force

Achieving True Flexibility for the Joint Force Commander

Lt Col Matt J. Martin, USAF
CDR Brian Rivera, USNR
Maj Jussi Toivanen, Finnish Army

As opposed to finding independent solutions, we are trying to find joint, collaborative solutions that best support the joint warfighter in any spectrum of war.

—Gen John Corley, USAF, Retired
Commander, Air Combat Command

The US military has never been more capable. In the past, we found sophisticated jammers, sensors, and command and control (C2) systems only at the operational level of war (typically

4306 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

as part of the air or maritime components). Today they appear in the backpacks and vehicles of frontline troops. Similarly, although the highest-end capabilities were once tasked only against strategic objectives, today's C2 and data-distribution systems allow operational-level capabilities to provide direct support to ground troops. Even though these capabilities permit unprecedented joint flexibility and recent changes in joint doctrine make possible the joint tasking of tactical assets, many of the latest capabilities remain organized and controlled as if they can support merely a single component.[1] Key examples include ground-based signals intelligence sensors and organic airborne reconnaissance assets not organized, trained, or equipped for independent availability to the joint force. As we will see below, such assets as the Army's MQ-1C Gray Eagle or man-portable electronic jammers are intended to deploy as part of a larger single-component force, with little consideration given to their overall joint utility.

But what if things were different? What if the joint force commander (JFC) had not only knowledge—based on the expertise and experience of joint planners—of the capabilities of all our tactical and operational systems but also the tasking tools and authority to incorporate specific capabilities into the operational design of a joint campaign? Conversely, what if tactical commanders enjoyed the same fidelity of tactical control over joint assets as they do with their own organic assets? (The joint assets would include not just traditional, direct-support assets such as close air support [CAS] but the full range of joint capabilities.)

We face a future of severe fiscal constraints, rapidly emerging regional conflicts (consisting of both asymmetric and near-peer foes), and the likely need for both joint and coalition partnerships in any operation. Consequently, professional joint planners must seek new ways to take advantage of all existing US capabilities—regardless of echelon or service—and increase flexibility for the JFC. Many smaller Western nations are familiar with this problem, one born of limited forces that must fill multiple joint requirements. Finland is one such country, and Finnish operational thinking may prove instructive. This

4307 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

article uses the Finnish model as a case study to support three key reforms to traditional US force presentation towards a more capable joint task force (JTF): (1) enabling JTF planners to take a capabilities-based approach to requesting forces, (2) making it possible to separate traditionally organic forces from their parent units for small-scale deployment and employment, and (3) increasing the flexibility of joint-relevant forces (the use of both operational forces that do not normally provide direct support to tactical units and traditionally tactical units as operational assets) by increasing their connectivity to make them more supportive of and responsive to the full spectrum of joint C2.

The Joint Relevance of New Tactical Capabilities

Recent years have seen a tremendous increase in sophisticated capabilities fielded at the tactical level. Take, for example, the ITT Electronic Systems Counter Radio-Controlled IED [improvised explosive device] Electronic Warfare (CREW) 2.1 vehicle-mounted jammer (up to 25,000 of which are on contract for purchase by the US Army). It uses a digitally controlled, 30-watt transmitter that can cover the entire HF/VHF/UHF spectrum, jam multiple frequencies simultaneously, and cover both broad areas and spot targets.[2] In situations involving asymmetric targets near a border or those in which the JFC possesses insufficient electronic warfare (EW) capability at the joint level to attain the desired effects, these types of systems could act as key gap-fillers in a joint operational plan. They also pose problems for joint planners in terms of electronic deconfliction and fratricide.

4308 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Marine carrying a Thor II backpack-mounted counter IED jammer. (Reprinted from "Marine Corps Photos," US Marine Corps, 13 February 2012, http://www.marines.mil/Photos.aspx?igphoto=768.)

Tactical intelligence, surveillance, and reconnaissance (ISR) has also seen huge advances in miniaturized capabilities. For instance, the AN/MLQ-40 vehicle-borne multisensor signals intelligence system can "detect, monitor, identify and selectively exploit Radio Frequency (RF) Signals for Intelligence information providing situational awareness and potential targets for Tactical Commanders. The exploited signal data can be relayed via voice or data through the organic Wideband Beyond Line of Sight (WBLOS) SATCOM communications system."[3] With both wide-area coverage and the ability to distribute data to joint exploitation centers, these ground-based sensors could significantly add to the JFC's collection capabilities. The joint use of such a system, however, would require distribution of ISR data to the joint and opera-

4309 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

tional levels as well as the traditional tactical level. Operational C2 mechanisms must also be in place to task these systems as joint assets.

US Army photo

AN/MLQ-40 Prophet

Perhaps the most capable system fielded at the tactical level is the US Army's MQ-1C Gray Eagle. A variant of the General Atomics MQ-1 Predator, the Gray Eagle is a 3,600-pound airplane with a 56-foot wingspan, a 25,000-foot service ceiling, and a payload of up to 400 pounds of external stores. The Army has a long-term plan to equip each of its divisions with a company of 12 Gray Eagles.[4] Ultimately, these aircraft achieve a true multirole operational capability, including air-to-ground fires, ISR, and EW.[5] The Army plans to procure and field this capability as an aviation support element for use as an organic asset. Despite efforts to make this platform available for joint use (see the section on Task no. 11, below), it is not yet available to the JFC as a separate, taskable capability. Since the Gray Eagle flies above the coordinating altitude in joint airspace, we already face the problem of incorporating it into the joint airspace planning process. Tasking the Gray Eagle as a joint operational asset will require putting in place the same type of tasking and C2 tools that already exist for Marine Corps and Navy aviation (more on that later).

4310 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

US Army photo

MQ-1C Gray Eagle

Recent Conflicts and the Need for Joint Flexibility

The recent operation in Libya or the ongoing North Atlantic Treaty Organization (NATO) operations in Afghanistan are the types of scenarios in which these capabilities could prove useful at the joint level. In Operation Unified Protector, for example, during enforcement of the no-fly zone over Libya, the US Navy and other NATO maritime forces supported the air component even as they carried out their own maritime tasks. This support included supplying C2 for tactical air assets and conducting surveillance missions with tactical unmanned aircraft.[6] However, since neither US nor NATO doctrine specifies a mechanism for either the JTF headquarters or a supported component to incorporate these capabilities into joint-level plans, key joint tasks tend to go to components that will address them with single-domain solutions.[7] Although a few areas of traditional joint integration (such as CAS and tactical mobility) have mature tactics, techniques, and procedures (TTP) and liaison structures for effective integration, other areas such

4311 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

as ISR, EW, and multiechelon communications do not. Therefore, joint support at the tactical level in these areas tends to occur on an ad hoc basis with less-than-optimal coordination. Opportunities to plan for joint cross-cue, provide a mechanism for dynamic joint retasking, or simply synchronize joint operations and increase efficiency can be lost.

Another example of the need for greater joint flexibility at the tactical level took place during surge operations in Operation Iraqi Freedom. This period focused on classic counterinsurgency operations instead of corps-level planning. Every battalion commander needed the ability to plan and execute operations independently—tasks that often depended on the predictable availability of operational-level capabilities, regardless of the priority of that particular action in the overall scheme of maneuver.[8] Maintaining the integrity of tactical-level operations and ensuring that joint-level assets promised during the planning phase remain available for execution, regardless of changes in the operational picture, were more important to the overall success of a counterinsurgency campaign than constantly shifting assets to meet perceived operational priorities. Future counterinsurgency JFCs might therefore be willing to risk inefficiency at the operational level rather than pull promised joint assets from tactical commanders just when they need them most.

Thus, in Iraqi Freedom, the traditional model was inappropriate to the new fight. Not only did tactical commanders have difficulty planning their operations 72 hours or more in advance (to comply with the doctrinal 72-hour air tasking order [ATO] cycle) but also the sudden removal of a capability in favor of higher priorities could make it impossible for tactical commanders to carry out their operations.[9] Ad hoc solutions were created to overcome doctrinal deficiencies in Operations Iraqi Freedom and Enduring Freedom, but the doctrinal model remains the same. Moreover, since the joint force air component commander (JFACC) had no visibility on the operations conducted at the battalion level—and no mechanism to understand the real-time ISR

4312 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

needs of tactical commanders—he could not respond to emerging ISR requirements.[10] The traditional liaison elements in place (e.g., air liaison officers [ALO], an air component coordinating element at the corps level, and a battlefield coordination detachment at the combined air and space operations center [CAOC]) concentrate for the most part on translating apportionment into allocation—primarily to provide CAS to the Army. They are neither set up nor intended to offer real-time coordination of joint ISR, EW, and C2.

Similarly, the fact that tactical commanders had no real-time visibility on the status of operational ISR assets, even when those assets were in the local area, meant that they would have no warning prior to reallocation and no way to fill that gap with other available assets. Joint doctrine gives tactical commanders a means of accessing the full range of joint fires, but for ISR, communications relay, and EW, a doctrinal or procedural solution remains elusive although ad hoc solutions were devised during Iraqi Freedom (see the section on intelligence liaison officers [ILO], below).

Expanding Traditional Joint Air Tasking to Include New Tactical Capabilities

In traditional joint operations, during which a component commander has organic air assets not needed for organic tasking, those assets are typically made available to the JFC. In fact, according to Joint Publication 3-30, *Command and Control for Joint Air Operations*, the JFC has the authority to make available components' organic air forces for joint tasking. To determine which ones to provide for joint air operations, the JFC will consult with component commanders and identify excess air capabilities. Typically, the commander of Air Force forces is designated the JFACC and becomes the supported commander for strategic attack, air interdiction, and airborne ISR.[11] For instance, carrier strike group F-18s that belong to the joint force maritime component commander (JFMCC) would typically be "retained for employment in

4313 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

support of the assigned joint maritime missions."[12] When the JFMCC has excess capabilities—F-18s not required for assigned joint missions or for fleet defense—he or she will give them to the JFACC via the joint air tasking process.[13]

The primary mission of the organic air capabilities of the Marine air-ground task force's (MAGTF) aviation combat element (ACE) is to support the task force's ground combat element. During joint operations, the MAGTF's aviation assets normally support its mission requirements, and these organic air requirements in support of subordinate elements within the task force are prioritized and scheduling conflicts are resolved by the MAGTF commander.[14] In the unlikely event the MAGTF has excess air capabilities, those assets will be given to the JFACC for theater air tasking, including air defense, long-range interdiction, and long-range reconnaissance.[15]

Once the components identify and provide excess air capabilities (including unmanned aircraft systems [UAS], typically identified as an ISR asset) to the JFC, the JFACC becomes the component responsible for planning, coordinating, allocating, and tasking. In accordance with JP 3-30, "the JAOC [joint air operations center] should request ISR support from the JFC or another component if available assets cannot fulfill specific airborne ISR requirements. It is imperative [that] the JFACC remains aware of all surveillance and reconnaissance capabilities that can be integrated into joint air operations."[16] But this does not necessarily mean that all resources are pooled for maximizing the JFC's theater-wide surveillance and reconnaissance effects. In the case of Marine UASs (as well as Army UASs), these are considered organic ISR assets—even if their parent unit is neither tasked nor deployed.[17] Indeed, given the existence of an identified best practice of pooling and optimizing the use of organic UASs to support Marine operations, the Marines do not extend this practice to the joint level. This is true even when Marine capability is present in a joint operations area but Marine ground operations have not yet commenced.[18] That is, even

4314 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

though the MAGTF contains highly capable ISR assets, if it has not yet begun ground operations, those assets will sit idle.

Once operations begin, though, the Marine unmanned aerial vehicle squadron (VMU)—a UAS unit attached to the MAGTF—will provide, through the MAGTF's ACE, the task force commander with UAS capability in either a general or direct-support role. Under general support, the ACE commander will supply UASs to the force as a whole, ensuring that all MAGTF elements have the best access and that "priority of support to subordinate elements will likely go to the unit that is the main effort."[19] When the ACE and VMU operate in a direct-support role, UASs support a specific, designated unit.[20]

The Marines of the I Marine Expeditionary Force (Forward), for example, became both the MAGTF and Regional Command–Southwest during Enduring Freedom and faced an ISR resource-management challenge. The problem involved optimizing the use of ISR capabilities against coalition and NATO requirements. The solution included making organic aviation assets available to the priorities of required mission sets. Essentially, the Marines integrated air reconnaissance UASs in concert with other functions of aviation.[21]

Integrating Operational Capabilities at the Tactical Level—ALOs and ILOs

Another instance of increased flexibility came in the form of the ILO in Iraqi Freedom and Enduring Freedom. Beginning in 2006, the US Air Force began to deploy experienced ISR officers and noncommissioned officers to divisions and regional commands in Iraq and Afghanistan as part of the ALO contingents. Their purpose, although not yet enshrined in a joint doctrine document or tactics manual, was to improve the integration of the Air Force's ISR capabilities into Army and Marine tactical operations, assist with the planning of the use of those assets in ground operations, and optimize their employment

4315 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

when tasked to provide direct support. According to Lt Gen David Deptula, former USAF/A2, this partnering brought about

> better understanding and results for the collection requirements of ground commanders; improved partnering between ground force intelligence staffs, CAOC ISR division analysts, and . . . [distributed] analysts to work time-sensitive analytical questions pertaining to current operations; and exceptional situational awareness for ISR crews regarding the details of current operations in which they will participate.[22]

During Iraqi Freedom and now in Afghanistan, the Air Force embedded ILOs within each deployed division as well as at key nodes such as the JTF headquarters and special operations forces headquarters—and with maneuver units engaged in high-priority operations. Typically, they were embedded in ground units as a means of better synchronizing operational ISR support with maneuver and fires. They also took advantage of the inherent ISR capabilities of joint-fires assets such as fighters with advanced targeting pods, incorporating them into the tactical-collection plans of ground units. This type of capability, which has come to be known as nontraditional ISR, supplied a key gap-filler for units engaged in ISR-intensive counterinsurgency operations.[23] However, the use of ILOs was never added to joint doctrine or sourced as part of ALO unit-manning plans. The utilization of ILOs in Iraqi Freedom and Enduring Freedom demonstrates that adding new capabilities is not enough to increase joint flexibility and effectiveness. Rather, we need a means—typically operator-centric—of planning for the use of these capabilities, leveraging them in complementary ways with other capabilities, and integrating them into dynamic operations.

The Finnish Model: An Example of Joint Flexibility

The main points in strategy for transformation of the Defense Forces are that the size of the Armed Forces must be equal with the tasks and budget, they must develop equal effectiveness with fewer resources, and they must build cooperation within the nation.

—Gen Ari Puheloinen
Commander, Finnish Defense Forces

4316 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

In recent years, the Finnish Defense Forces (FDF) have faced wide structural transformation because of aging equipment, the high cost of modernization, and the expensive nature of crisis-management operations. To counter these issues, the FDF is making joint flexibility a primary consideration in the acquisition process, with the goal of moving away from dedicated service capabilities towards more commonality and better cost-effectiveness. In fact, joint operations have been at the heart of Finnish operational thinking since World War II. Central to the FDF are terms like "service shared operations" or "service shared fire."[24] Thus, "key areas of Finland are secured in all circumstances, aggression is defied and if needed combatted in a JOINT operation in order to accomplish the end state."[25] Figure 1 shows the C2 structure of the FDF along with the level of joint organization.[26]

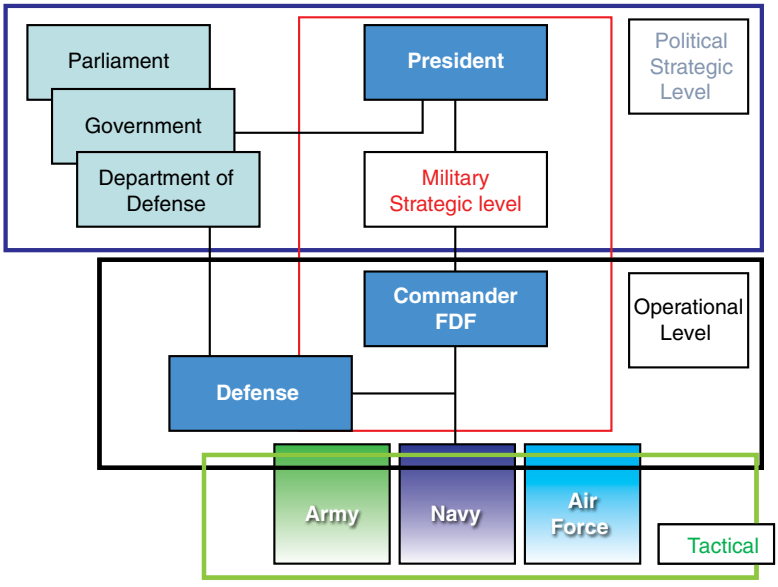

Figure 1. FDF structure. (From Col Pasi Kesseli, "Use of Common Capabilities in the Winter and Continuation War" [lecture presented at the Finnish National Defense University, 5 November 2012].)

The FDF leverages capabilities from the Army, Navy, and Air Force, as well as from a set common capabilities (fig. 2). These capabilities

4317 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

(mainly joint fires, ISR, and EW), organized along component lines and considered common to joint operations, constitute the bulk of the FDF.

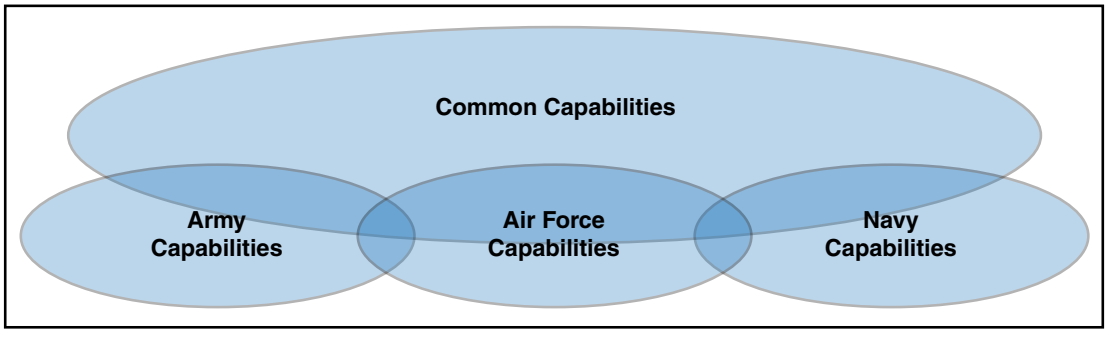

Figure 2. FDF capability organization. (From Kenttäohjesääntö, Yleinen osa, *Puolustusjärjestelmän Toiminnan Perusteet* [Field Manual, General Part, *Basic Structure of the Defense System*], 30.)

Common capabilities are allocated and assigned at the joint level, and the Defense Command plans their use—including service capabilities for use by the commander. Along with key enablers, the Finnish model prescribes joint integration based on a set of common principles for acquisition, training, and organization.[27] The key difference here between the US and the Finnish model is that although Finnish planners can reach down to the tactical level to pluck needed capabilities from larger parent units, the US planner cannot tap into something like the MQ-1C without tasking the entire division to which it belongs.

The Finnish service chiefs are generally responsible for planning the independent use of service (noncommon) forces. However, even these forces will be allocated to the Defense Command when needed. This would include any operation to "defend Finland and will be led by the Defense Command using the capabilities of the Army, the Navy and Air Force in addition to the common capabilities."[28]

Defense Command prioritizes the use of common capabilities in national/joint operations and returns any excess to the services or to the regional commands. In some cases, the command can delegate a task

4318 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

to a service.[29] During joint operations, Defense Command will ensure a high level of situational awareness for all players by integrating the recognized air, land, and maritime pictures into a common operating picture (COP). The command will then either act as the JTF headquarters or allocate capabilities to operations led by the services. Doing so enables the FDF to mass Finland's limited combat power and concentrate it against the aggressor's most critical vulnerability or center of gravity. Defense Command will also use centralized control with a flat command structure to make decisions more rapidly than the aggressor and operate inside his decision-making cycle. Finnish joint operations are therefore task-oriented, using only those capabilities needed to reach culmination. Other capabilities are then returned to the supporting services.[30] In all cases, though, Defense Command will own and distribute the real-time COP and coordinate all operations.

A common Finnish scenario involves the need to move land forces along the coastline to assume an advantageous defensive position. In this case, Defense Command will delegate operational control to Army headquarters. In case of major maneuver, the command will use forces with common capabilities to support the maneuver and may also assume operational control of supporting forces (such as the Navy or Air Force) to support the Army. These would typically be key enablers such as joint fires, information warfare, or ISR.[31]

Admittedly, Finland is a small country with limited resources, and many people might argue that almost any organizational structure would work. However, since future Department of Defense (DOD) budgets will probably continue a downward trend, it is informative to examine smaller militaries and the way they maximize capability with limited resources. This is the primary driver behind the creation of joint "common capabilities." Strategically, Finland must be able to build up and employ joint forces rapidly against single tasks—even if those forces are normally organized at the tactical level or are otherwise organic to the service. Like Finland's Defense Command, the US DOD faces increasingly constrained budgets, smaller force structures,

4319 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

and the need to organize joint and coalition task forces quickly to respond to small and often asymmetric crises. Thus, a JFC's ability to tap directly into tactical-level units—particularly when they possess key enabling capabilities such as C2, ISR, and EW—could be of key importance. The DOD may benefit greatly from the lessons of the Finnish model. In fact, the Army and Air Force have already given some thought to this type of arrangement for unmanned aircraft.

Task No. 11 and the Use of Organic Unmanned Aircraft Systems

On 30 June 2008, Gen John Corley, commander of US Air Combat Command, and Gen William Wallace, commander of US Army Training and Doctrine Command, agreed to a new concept for the employment of theater-capable multirole unmanned aircraft. This concept grew from an earlier task (no. 11) from the Army–Air Force Warfighters talks in which the chairman of the Joint Chiefs of Staff gave the two services the task of finding a better way to employ these highly capable systems in joint operations.[32] The concept called for doctrine, organization, and training, as well as material, leadership, and personnel changes to the Air Force MQ-1/MQ-9 and the Army MQ-1C programs. The goal called for all three platforms to function seamlessly as joint air assets controlled by the JFACC (when deemed necessary by the JFC) and as "near organic" systems when the JFC determined that a ground commander should receive direct support. Figure 3 identifies the data, TTPs, and C2 links needed to execute the concept.

4320 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

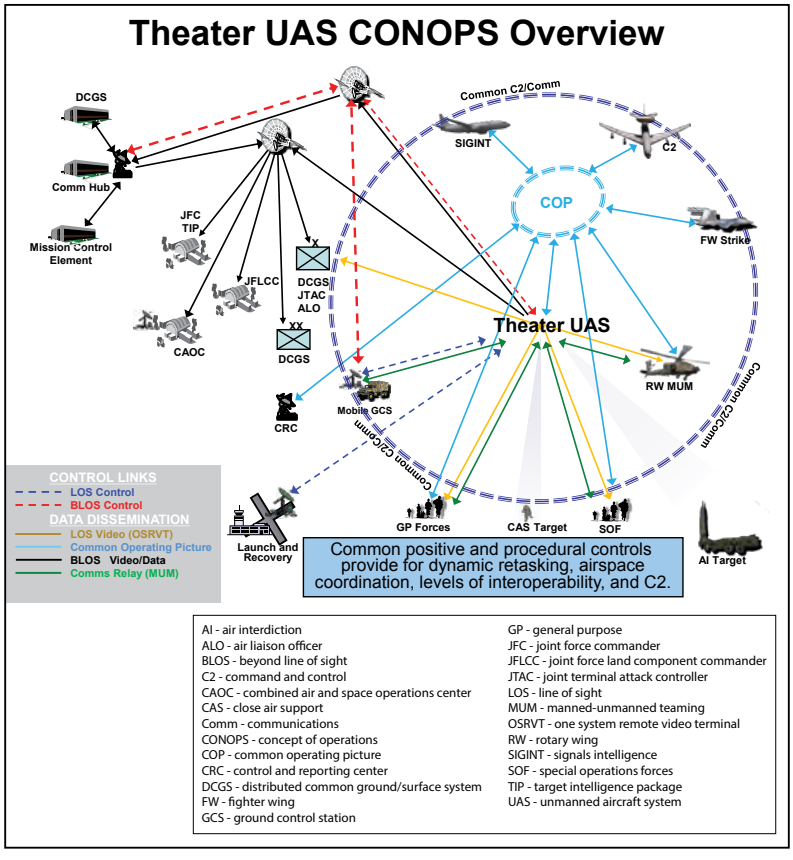

Figure 3. Task no. 11 operational view. (Reprinted from Air Combat Command and Training and Doctrine Command, *The Multi-Role, Theater-Capable, UAS Enabling Concept* [Hampton, VA: Air Combat Command, 2008], 4.)

The idea behind the concept entails building the maximum possible flexibility into these systems by ensuring that the ISR data they produce is compatible with both Army and Air Force ISR exploitation systems as well as Link-16 and Blue Force Tracker tactical data links. The systems should also be able to distribute their ISR data both locally and beyond line of sight. They should respond to both tactical and operational echelons of C2. Task no. 11 requires that operators of these systems be well versed in the joint TTPs and terminology needed for both joint and component integration.

4321 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The US Army and Air Force have since taken steps to implement the concept by making adjustments to their organize/train/equip efforts. Changes have been made to joint doctrine and TTPs (e.g., the procedures needed to incorporate Army assets into the JFACC ATO in the same manner as Navy and Marine air assets).[33] The Air Force has also taken advantage of this work to improve support provided to ground units in Afghanistan through habitual association with supported units as well as better visibility and understanding of tactical ground operations. The Army, however, has not yet had the opportunity to demonstrate joint integration of the MQ-1C and, therefore, has been able to test the concept only through war gaming.[34]

Recommendations: A Scheme for Greater Joint Flexibility (Plug and Play)

Obviously, the US military is much bigger and has much greater capacity than the FDF. Consequently, under what circumstances would the JFC need to tap into tactical capabilities? Consider the following three vignettes:

1. *A small, regional conflict that threatens a nonvital interest of the United States or its allies but for political reasons requires US involvement*. Operation Unified Protector in Libya offers one such example. In this case, it was politically unacceptable for the United States to take the lead with offensive forces or to introduce ground troops directly into the conflict, despite the fact that a US commander directed the main effort and that the vast majority of key enabling capabilities came from America.[35] According to Lt Gen Ralph Jodice, JFACC for Unified Protector, his operation suffered from gaps in ISR and EW due to the lack of the capacity of forces normally available in a large US operation (e.g., U-2s or RQ-4s). In the future, when high-level ISR assets are not available, having access to mitigating organic maritime or land-based capabilities for direct joint tasking could prove decisive.[36]

4322 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

2. *The deterrence phase of what is expected to be a major US operation*. In this case, the United States may need to rapidly demonstrate its ability to respond to regional aggression with flexible deterrence operations while awaiting a larger deployed force. There simply may not be time for a JTF commander to wait for high-end operational capabilities to arrive on station. The JTF, therefore, would need to take maximum advantage of any capabilities that might already be in-theater to produce a decisive deterrent effect. As it stands, organic capability resident within a nontasked or not-yet-active parent unit is not directly available to the JFC.
3. *Simultaneous conflicts breaking out in different areas of responsibility*. In this case, one of the operations may have a lower priority and thus cannot gain access to a significant number of operational capabilities. As in vignette no. 2, the JTF commander of the lower-priority conflict would have to make the best use possible of whatever capabilities are on hand—such as tapping into tactical-level ISR or EW without tasking the parent unit.

To ease the leveraging of tactical capabilities to satisfy operational-level needs in these vignettes, one would have to make significant changes to joint planning doctrine, joint operational doctrine, and the manner in which those forces are made available to the JFC for tasking.

Reform No. 1: Capabilities-Based Planning

Currently, forces are identified for apportionment through their primary maneuver echelon. For example, a JTF planning staff might learn that a brigade combat team is on the apportionment list, but without amplifying information on the internal capabilities of that team, the JFC would have to rely on the knowledge and experience of the planning staff. That would work fine if an Army officer with appropriate experience happens to be on the team. If no such person is available, then those capabilities would remain invisible to the JTF planning staff. To correct this situation, we need to identify joint capabilities as part of their parent maneuver units during the apportion-

4323 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

ment process. Thus, when a JTF's J-5 staff is planning an operation and receives global force management appendices with a list of apportioned forces, the appendix could be expanded to include detailed information about joint capabilities. This addition might take the form of another column with the relevant information (see the table below). J-5 planners would also need more training so they will understand the nature of these capabilities and include them in their plans.

Table. Hypothetical global force management appendix identifying joint capability

APPENDIX 1 (U.S. Army Apportionment Tables) to Section IV (Apportionment of Forces) to Global Force Management

FMID - force management identifiers
FMV - full-motion video
JTF-PO (SPOD) - joint task force port opening seaport of debarkation
RLD - ready-to-load date

Reform No. 2: Independent Presentation of Small, Traditionally Organic Units

Currently, submaneuver units (i.e., those not presented as independently maneuverable) are bundled with their higher-echelon main-

4324 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

maneuver unit. Consequently, a company equipped with tactical jammers would be presented only as part of a larger unit (brigade or division). If the JTF needs access just to the company equipped with jammers, then the force provider may have no mechanism to mobilize and deploy it independently of the parent unit. (This may be the case even though the company will not be called upon to maneuver independently of a larger force—if, for example, the company is needed at a coalition base on a border.) Since we routinely deploy and task small units with operational capabilities from all four services, this should simply be a matter of extending this ability to units that do not traditionally deploy on their own.

This would constitute a "plug-and-play" approach to joint capabilities. In the example of an infantry company with backpack jammers, the JFC will need to access that unit via the time-phased force and deployment data sourcing process in order to include it in the operational plan for purposes of C2, sustainment, and so forth. Then, as the JFC designs the overall C2 structure, the unit could be aligned with the appropriate tactical C2, basing, and sustainment elements—and included in the support plans of the units responsible for those basing locations.

Reform No. 3: Flat and Flexible Joint Command and Control

For maritime capabilities, we can expect a maritime component commander with associated tactical C2 of maritime forces. The maritime component, therefore, can assume the task of using maritime organic capability as a joint asset. But the JFACC should be able to control air assets normally organic to the land component—or do so in the absence of land forces that would exercise tactical C2. For example, as part of Task no. 11, the enabling concept specifies the need for an MQ-1C company to interface with a CAOC, integrate into the ATO and master air attack plan process, and receive those ATO instructions. The air component's tactical C2 elements would then control that company.[37] This process drives training and equipment as Gray Eagle companies take on the task of preparing to function as joint air assets.

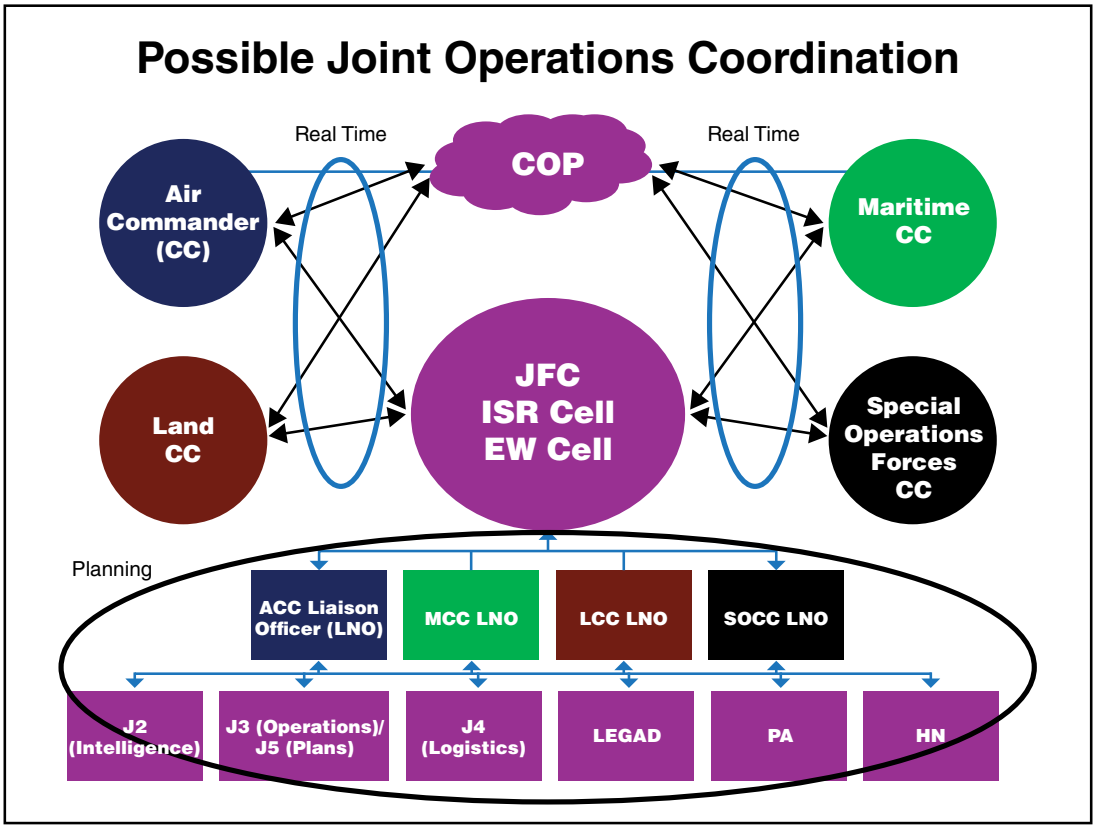
4325 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

For small land units that will deploy without their higher-echelon tactical C2, the issue becomes a bit trickier. They must either interface directly with the JTF headquarters or attach themselves to another component (perhaps special operations or the JFACC for ISR). In either case, they would need the connectivity to interface with the appropriate C2 network as well as training in the appropriate joint TTPs. In most cases, though, the TTPs already exist (e.g., joint CAS). So the main task amounts to training for units not previously trained to function as joint assets.

A practice of providing the JFC with daily status reports of high-demand, low-density organic assets already exists. For instance, each day the US Navy reports the status of SM-3 and Tomahawk land-attack missiles within the fleet to the Joint Staff and to the geographical combatant commanders. Without integrated solutions, this data has to be sent via PowerPoint briefs or Excel spreadsheets.[38] The commanders, therefore, are aware of the numbers and types of SM-3s and missiles aboard ships operating in their area of responsibility and have the means to task those weapons, but the information sharing is less than optimal. We need a better solution—the ability to inject data into the COP—to allow better JFC tracking and tasking.

For the converse problem of better support to the tactical commander, the effectiveness of ILOs embedded with ground units has been well documented. We should expand this liaison presence to mirror the CAS approach, with liaisons at every echelon from division to battalion. These ILOs not only should be experts on operational ISR capabilities (both airborne and within other domains) but also should have the training and authority to match tactical ISR desired effects to available sensors and exploitation elements—and even exercise tactical (but not terminal) control over operational sensors, just as forward air controllers exercise tactical control over CAS assets. However, we would not expect ILOs to exercise air traffic control, as we do with forward air controllers.

4326 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING



If manning restrictions prevent the training and deployment of more ILOs, then the role of the joint terminal attack controller should be expanded to include ILO and EW liaison duties. Doing so would require both additional training and improved connectivity with ISR/EW collection platforms and their associated exploitation elements. These elements (i.e., the distributed common ground/surface systems) could then be leveraged to provide greater ISR fusion and analysis (as well as knowledge of sensor and platform capabilities) to the controllers in order to ease their burden and increase their capabilities. Finally, we need real-time coordination at the joint level in the form of ISR and EW coordination cells that perform a number of functions:

- Provide real-time joint coordination to mass joint sensors and jammers on specific objectives.
- Facilitate cross-cueing of joint ISR and EW.
- Offer real-time guidance to components to change the weight of effort against dynamic targets inside the execution phase.
- Analyze component ISR products to arrive at fused, joint intelligence assessments and feed the decision-making process.
- Ensure that all players tasked against joint objectives maintain and facilitate a high level of situational awareness.
- Assist the J-3 and J-5 staffs with planning for the use of joint capabilities.

Figure 4 shows a possible coordination scheme among joint-level execution, planning, and the various components. We should note that coordination cells at the joint level will not act as tactical C2 agencies, nor will they provide guidance directly to tactical units. The components will still fill those roles. Rather, joint cells will coordinate with ISR and EW cells within the component headquarters to conduct the above functions. Similarly, large-scale operations with sufficient forces to obviate the need to tap into tactical-level forces for joint tasks may not need these cells. For smaller-scale operations described in the three vignettes, however, small coordination cells on the JTF level will

4327 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

be in the best position to derive maximum efficiency and flexibility of joint forces.

The Life You Save Could Be Your Own

The United States and its allies face uncertain times—those marked by pop-up regional conflicts, shrinking defense budgets, and insufficient forces to carry out assigned tasks. We may no longer be able to afford the luxury of retaining our most sophisticated capabilities as organic elements of a component or maneuver unit. At times, for reasons of politics, finances, or simple priority, a JTF commander will need access (i.e., visibility during the planning process, the ability to task tactical units independently of their parent maneuver units, and operational C2 of traditionally tactical assets) to the full capabilities of all assigned forces. As a steward of our national resources, the joint force would be remiss if it did not explore every possibility to provide just that. As a result, joint capabilities must be available not only for joint planning purposes but also for joint tasking, even in the absence of their parent maneuver units in a traditional C2 architecture.

At the same time, we must make sure that the tactical commander has access to the most sophisticated operational capabilities when appropriate and available. Doing so will involve not only simple connectivity but also liaisons and forward controllers who are experts in the application of joint military power—individuals who have the visibility and authority to leverage high-end joint capabilities to great tactical effect. Perhaps we cannot predict the next conflict, but we can build maximum flexibility within the joint force to fight it. ✪

Notes

1. For example, according to the latest version of Joint Publication (JP) 3-30, *Command and Control of Joint Air Operations*, 10 February 2014, http://www.dtic.mil/doctrine/new_pubs/jp3_30.pdf, "Theater-capable UASs . . . can be used to support the JFC" (III-32). Furthermore, JP 3-32, *Command and Control for Joint Maritime Operations*, 7 August 2013, http://www.dtic.mil/doctrine/new_pubs/jp3_32.pdf, notes that "the JFMCC [joint force maritime component commander] provides a unique complement of sensors and sensor fusion capability to support joint requirements and advocates for the use of other component and national assets to provide optimum support to maritime operations. Sonar capabilities and the

4329 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

ability to relocate surveillance and reconnaissance assets may provide additional options to the JFC. Close coordination with other component commanders and the communications system directorate of a joint staff (J-6) early in joint planning is essential to aligning architectures with platform and sensor employment plans to optimize intelligence, surveillance, reconnaissance, and associated processing, exploitation, and dissemination systems throughout the joint force" (II-7).

5. "ER/MP Gray Eagle: Enhanced MQ-1C Predators for the Army," *Defense Industry Daily*, 16 December 2013, https://www.defenseindustrydaily.com/warrior-ermp-an-enhanced-predator-for-the-army-03056/.

6. "Insitu ScanEagle Works with NATO on Libyan Missions," *Defense Daily* 251, no. 32 (16 August 2011), http://www.defensedaily.com/Assets/File/txt/DD_2011-08-15_17-31.txt.

7. "The JFC should attempt to meet the organic needs of the component commanders, while ensuring the JFACC has the assets available to execute JFC assigned JOA [joint operations area]-wide operations. These decisions will typically change as the phase of an operation changes. As with any joint capable asset, the JFC retains the authority to use any UAS asset to meet the needs of the JFC mission. How theater-capable UAS operations are managed and planned will vary based on the type and phase of an operation." JP 3-30, *Command and Control of Joint Air Operations*, III-32. Also, "sensor capability resident in the joint maritime force may support the joint force collection plan and may be integrated into the joint data network. Sensor tasking procedures, allocation of collection assets, and product dissemination should be determined early in the planning process." JP 3-32, *Command and Control for Joint Maritime Operations*, III-11. The following guidance is provided to joint-level collection managers with regard to tasking joint ISR assets: "The list of viable collection disciplines, systems, and sensors is reviewed for current availability (to include estimated downtime if not available) and the addition or deletion of capabilities. Coordination with adjacent and higher HQ and national agencies will determine the availability of theater and national resources." JP 2-01, *Joint and National Intelligence Support to Military Operations*, 5 January 2012, III-24, http://www.dtic.mil/doctrine/new_pubs/jp2_01.pdf. Typically, joint-level collection managers constrain themselves to operational-level ISR assets to collect against joint targets rather than trying to task an organic asset directly.

Lt Col Matt J. Martin, USAF

Lieutenant Colonel Martin (BA, Purdue University; MA, University of Denver) is a special projects officer assigned to the 28th Bomb Wing, Ellsworth AFB, South Dakota. He is responsible for integrating new and joint-urgent capabilities into the wing's MQ-9 combat operations as well as improving the realistic training of its MQ-9 crews. Lieutenant Colonel Martin is an MQ-9 pilot with more than 2,000 hours of combat experience in Iraq and Afghanistan. Previous assignments include chief of MQ-1/9 operations, Headquarters Air Combat Command; chief of airborne reconnaissance and electronic warfare, NATO Headquarters Air Command Izmir, Turkey; wing chief of safety and 16th Training Squadron director of operations, 49th Wing, Holloman AFB, New Mexico; and commander, 46th Expeditionary Squadron, Balad AB, Iraq. Lieutenant Colonel Martin is a graduate of Squadron Officer School, Air Command and Staff College, Air War College, and the Joint and Combined Warfighting School.

CDR Brian Rivera, USNR

Commander Rivera (BA, University of Colorado; MA, Air Command and Staff College; MBA, University of Phoenix; PMP [Project Management Professional], Project Management Institute; CSM [Certified Scrum Master], Scrum Alliance) is an integrated air and missile defenses (IAMD) subject-matter expert assigned to US European Command J3 IAMD. His active duty includes selection as a European and an African foreign area officer, serving three years at US Africa Command as the Kenya and Tanzania desk officer. He has extensive air operations experience, including a tour as a tactical evaluation project officer with the NATO commander for air, Ramstein, Germany; a three-year assignment as the master air attack plans chief at the 603rd Air and Space Operations Center, Ramstein, Germany; the air logistics operations officer at Commander US Naval Forces Europe–C6F, Naples, Italy; and an F-14 A/B/D instructor and F-14 demonstration team member.

The Awkward Embrace

Col Suzanne M. Streeter, USAF*

We don't just celebrate diversity. . . . We embrace it!

—Gen Mark A. Welsh
Chief of Staff, US Air Force

The Air Force is pursuing diversity as a mission imperative, recognizing that individuals who think alike might not resolve future complex problem sets. These challenges range from unrav-

*The author profusely thanks Dr. Kimberly Hudson; Ms. Kimberly Streeter; Col Jill Singleton; COL Gene Kamena, USA, retired; Lt Col John Yourse; and Dr. Elizabeth Woodworth for their reviews, edits, and frank discussions on this topic. Thanks also to Ms. Kimberly Streeter for her inspiration on the title.

eling an intelligence problem at the tactical level, through developing a campaign plan against a near-peer competitor at the operational level, to creating policies at the strategic level. Recent efforts have attempted to integrate diversity measures into Air Force culture, including Air Force instructions to codify "diversity [as] a military necessity."[1] Most Airmen, however, are more likely to view "diversity" as another top-down initiative accompanied by computer-based training, checklists, and rules-based compliance rather than recognizing it as a game changer for the Air Force. Even those who discern that diversity is important for the mission are often unable to articulate why this is so. The few who realize its importance or recognize groupthink in their inner circle often do so late in their careers.[2]

Discordance exists between Air Force intentions vis-à-vis diversity and any effective programs and policies to retain and develop a diverse cadre of senior leadership. Issues lie ahead for the service, from retaining key demographic populations to inculcating diversity's importance to mission success. This article addresses such a key demographic—active duty women officers—as an exemplar of the Air Force's retention challenges with diverse groups. Nevertheless, the data reflects that many of the conclusions are equally valid or comparable for other minority groups. Even though the service has initiated formal diversity efforts, recommended policy and development programs may help develop and retain competent officers across the board. Ultimately, building a diverse Air Force leadership team—including retention of its female officers—must be a persistent leadership effort.

The Air Force's Diversity Challenge

Groupthink is the worst thing you can have when you have a problem. . . . If there are all male Caucasians sitting around the table, you have groupthink.

—Gen Philip M. Breedlove, USAF

4335 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The Air Force proudly touts its diversity numbers, including the fact that 18.9 percent of the overall active duty force consists of women and that about 27 percent of its members derive from minority populations.[3] However, its long-term retention of minorities remains problematic; retaining female junior officers is emblematic of this systemic issue (see figs. 1–4). As of 2008, the Air Force's retention rate for women officers was about 50 percent around the seven-year mark, whereas the men met this milestone at about the 12-year mark; after 12 years of service, women's attrition rate was 70 percent (fig. 1).[4] Male officers do not reach this level of attrition until the 21-year mark. Female line-officer O-6s are conspicuously small in number (figs. 2 and 3) (line officers are the backbone of the Air Force's cadre of senior leadership as group and wing commanders, center directors, and general officers). The numbers are not that much better when combined with the non-line-officers (fig. 4). Finally, as of 2008, 85 percent of all general officers were white males (fig. 2).[5] These diversity imbalances in terms of gender and minorities at the senior leadership level have implications for the Air Force's long-term operational and overarching organizational success, as discussed later.

Diversity: Meaning and Importance

The Air Force has designated diversity as an institutional competency; in other words, it is "expected of all Airmen, throughout their careers, and will be . . . needed to operate successfully in the constantly changing environment in which they function."[6] This particular institutional competency is defined as "a composite of . . . personal life experiences, geographic background, socioeconomic background, cultural knowledge, educational background, work background, language abilities, physical abilities, philosophical/spiritual perspectives, age, race, ethnicity, and gender."[7] In July 2012, the Air Force acknowledged that "diversity is a leadership issue" and that leaders should develop "Airmen with different backgrounds and perspectives so [that] they continue to grow and thrive in the Air Force" because diversity "enhances mission readiness and is a national security imperative."[8] In July 2011, Gen Norton Schwartz, former chief of staff of the Air Force, asserted that "diversity should not be an end unto itself, but rather one of the means toward our broader desired state of enhanced effectiveness as an Air Force."[9] In spite of these strategic words, the service has not presented a clear case for how diversity improves mission readiness and national security, nor has it addressed how those at the operational and tactical levels should leverage diversity to enhance their mission success. Diversity is important to mission readiness and national security in terms of demographically representative leadership, enhanced civil-military relations with a diverse civil society, and the leveraging of diversity as a demographic mission necessity.

Representative Leadership

The Military Leadership Diversity Commission found that "officers were generally less demographically diverse than both the enlisted troops they led and the civilian population they served."[10] This situation could lead to "invisible privilege"—a condition in which a dominant group cannot comprehend those who do not fit the "norm" of that culture. A relatively homogeneous senior leadership cadre can

4340 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

become prone to "blind spots" in their dealings with the diverse enlisted corps and relatively diverse junior officer corps—not fully understanding what will resonate with these populations.[11] For example, current efforts to develop retention policies for women that emphasize monetary carrots do not necessarily reflect measures that will entice them to stay. In fact, in a 2002 survey, "only 4 percent of the women said pay and allowances were a critical factor in their decision to separate from the active duty Air Force"; other reasons honed in on family and leadership issues.[12] The military is one of the few US workplaces where women receive the same compensation as their male counterparts for doing identical jobs.[13] This equal-pay factor might not cross the minds of senior leaders who focus primarily on fiscally oriented retention efforts.[14]

Civil-Military Relations

Relative homogeneity in the senior officer corps also has implications for civil-military relations with respect to political leadership and the broader civilian society. As former House Armed Services Committee chairman Ike Skelton (D-MO) warned, "Those who protect us are psychologically divorced from those who are being protected."[15] Throughout history, tension has existed between military and civilian leadership. Increasing divergence in the attitudes of the Air Force and political leadership is foreseeable if the service's senior leadership cadre stays mostly homogeneous (given the continuation of a reduced presence of lawmakers who are military veterans). This trend has ramifications not only for garnering support for Air Force program requirements within Congress but also for resonating with the general public when the Air Force articulates its raison d'être.

Diversity and Military Necessity

Diverse teams are better than homogeneous ones at solving complex problem sets and thus can lead to mission success.[16] Indeed, cognitive diversity—thinking differently—has enabled "diverse groups of prob-

4341 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

lem solvers . . . [to have] consistently outperformed groups of the best and brightest."[17] Several studies of the civilian workforce suggest that gender diversity at the senior levels helps companies during a recession. One 2012 report that studied 2,360 worldwide companies from 2005 to 2011 demonstrated that "large-cap stock" companies (those making $10 billion annually) with at least one woman on their boards "outperformed those without women board members by 26%." It attributed this success to wide-ranging characteristics from "better mix of leadership skills" to "risk aversion," especially in a volatile market.[18] The benefits or success of gender diversity can be undermined by institutional biases or poorly implemented diversity programs.[19]

The military has no wide-range studies that examine whether diverse teams resolve complex problem sets better than nondiverse teams.[20] However, by concentrating on one segment of diversity—gender—one could make the case that women are increasingly necessary to conduct military missions. For example, male military personnel could not interact with Afghan women without violating cultural taboos. Marine Corps female engagement teams and special forces cultural support teams established in response to this matter produced unexpected benefits and valuable intelligence, including expanded impact since women "have considerable influence on their husbands, children and their community as a whole."[21] Gen Martin Dempsey, chairman of the Joint Chiefs of Staff, recognized this fact in January 2013 when he pushed for the lifting of the women's combat ban, assessing that "ultimately, we're acting to strengthen the joint force."[22] Not only have women been increasingly integrated in operations downrange but also a need exists for them to fill positions since fewer young people are available to meet military requirements. Specifically, only 15 percent of the US "youth population . . . is [eligible and] available to serve in the military."[23]

4342 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Moving toward Leadership Diversity

In her book *The Loudest Duck*, Laura Liswood asserts that "we need to get beyond the bricks and mortar of diversity as we know it—the committees, the employee networks, and the trainings. . . . These are all necessary, but not sufficient." She astutely observes that "diverse organizations require more sophisticated leadership . . . to reap the benefits of what true diversity can provide" and describes most corporations' approach to diversity as one of "Noah's Ark," whereby accession is the principal means of measuring diversity's success. However, there are often no effective programs to retain these minorities; even designed training can become counterproductive and the "unconscious handling of diversity can lead to diverse groups leaving."[24] As demonstrated below, this is the case for the Air Force as well.

The Air Force has directed much of its effort on gaining diversity via accession. In the case of gender diversity, female officer accession rates have averaged 24 percent (fiscal years 1997–2011).[25] However, the average percentage of females in the overall officer corps over the same time frame remained at 17.83 percent.[26] Disparities between accession and overall officer corps percentages for other minorities also exist. Given these facts, the article examines the Air Force's diversity efforts beyond accession, including three of the five priorities of the 2013 *United States Air Force Diversity Strategic Roadmap* that address the development and retention of a diverse force: "institutionalize diversity as necessary to mission success"; "develop a high-quality, talented and diverse total force (active duty, Guard, Reserve, and civilians)"; and "retain a high-quality, talented and diverse total force."[27] The planned actions to execute these goals have not gone far enough to ensure that Airmen understand how and why diversity is a critical part of solving complex problem sets.

The first priority is to "institutionalize diversity as necessary to mission success"—a multiyear and complex effort requiring persistent leadership efforts to communicate basic awareness (fig. 5). The next steps of influencing attitudes and changing beliefs—thereby evolving

4343 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Air Force culture—will call for even more dedicated attention and time. Efforts should include reviewing and changing policies to ensure the Air Force does not run "the risk of perpetuating the idea that organization members must always adjust to the organization, rather than the organization at non-mission-essential times adjusting to the diverse needs of its members."[28]

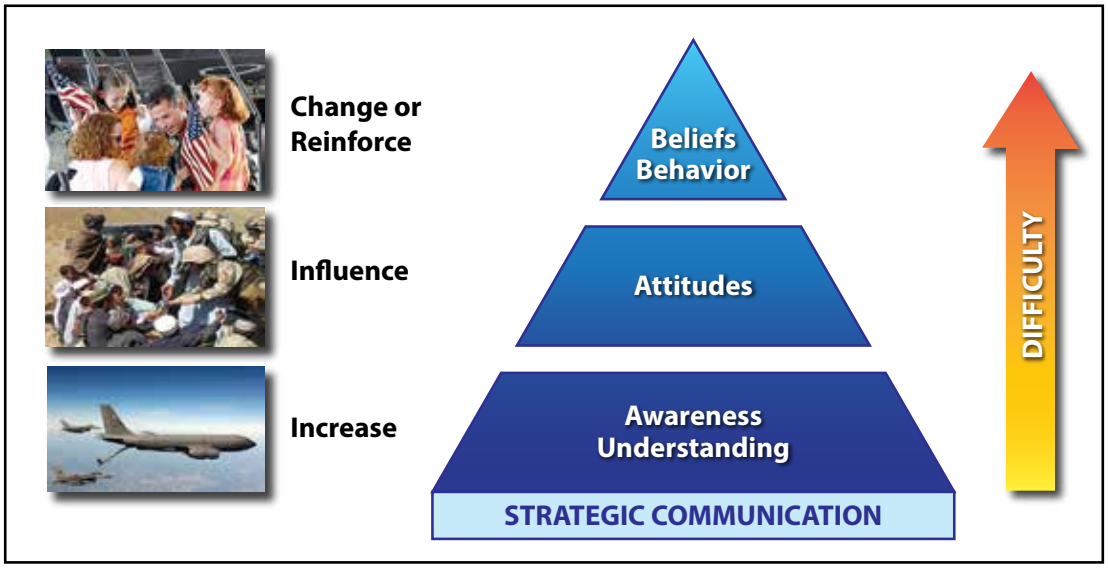

Figure 5. Desired effects of strategic communication. (Reprinted from USAF Public Affairs Center of Excellence, 2012.)

Current goals and actions mostly deal with Airmen feeling included instead of institutionalizing why and how diversity is necessary to mission success.[29] These actions include creating the Air Force Diversity Committee, major command–level diversity focus groups, and Air Force–wide guidance via the latest Air Force Instruction (AFI) 36-7001, *Diversity*, 20 July 2012.[30] Inclusion is important because "without an awareness of the cultural diversity of one's organization and the needs of different cultural groups, it is difficult to achieve an inclusive culture where members feel like they belong and believe they can succeed" (and stay).[31] Nevertheless, a backlash might emerge from the

4344 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

dominant population if the Air Force overemphasizes inclusion rather than diversity's importance since "framing social inequalities only in the context of the disadvantaged outgroup encourages prejudicial attitudes by privileged group members."[32] Several examples of this kind of reaction within the Air Force fall under the realm of the Equal Opportunity (EO) Office.[33] If diversity is to succeed, it must "complement, but remain separate and distinct from, Air Force Equal Opportunity compliance programs and activities," as noted by AFI 36-7001.[34] Most people regard the EO office as a resource to use when inclusion (or one might say, "tolerance") fails; therefore, relating diversity to an office associated with social ills would inhibit its evolution into a value completely embraced by the Air Force.[35]

Regarding the 2013 *Air Force Diversity Strategic Roadmap*'s second priority of "develop[ing] a high-quality, talented and diverse total force (active duty, Guard, Reserve, and civilians)," that plan has the right view of assuring the infusion of diversity and inclusion into many avenues of training and education. As mentioned previously, diversity cannot be reduced to computer-based ancillary training that involves individuals quickly clicking through to obtain their annual certificate. Headquarters Air Force Global Diversity Division is researching ways to implement a new learning framework following the 70-20-10 model created by the Center for Creative Leadership and adapted by Princeton University.[36] This model proposes that only 10 percent of students learn from "formal training," that 70 percent learn "from real life and on-the-job experiences, tasks and problem solving," and that about 20 percent learn "from feedback and from observing and working with role models."[37] Squadron Officer College's Leadership Department is implementing a 70-20-10 approach via a leadership elective that leverages Second Life, an online avatar-based program that virtually immerses students in historical leadership situations, allowing them to better grasp leadership styles.[38] Avatar-based scenarios like this one should be expanded to realistic diversity education and training insofar as no Air Force professional education offerings for officers have fully developed diversity education programs based on the 70-20-10 model.[39]

4345 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The 2013 *Air Force Diversity Strategic Roadmap* advocates mentoring as a path to "effectively operate in a global environment."[40] The online mentoring program that the service has had since 2009 could be a significant complementary tool because it allows mentors to see their protégés' official personnel records but presupposes that mentors have access to the Air Force Portal and that protégés are comfortable asking a senior officer to serve as a mentor.[41] A 2011 report by Women in International Security observes a "direct correlation between mentorship and professional advancement" but indicates that most government agencies "do not devote enough resources toward ensuring that existing programs are effective."[42] Instead, the Air Force could consider something like the OfficerWomen eMentor Program, which develops female officers and veterans.[43] In this program, a female officer can seek out a specific mentor or join a forum to discuss such issues as dual-military couples, efficiently regaining flight qualifications after giving birth, lactation in the workplace, or general career advice.[44] OfficerWomen eMentor has produced measurable results with a sister service. The Navy contracted with AcademyWomen, the program's sponsor, for a three-year pilot eMentor program for all uniformed female Sailors (officers and enlisted). Eighty-two percent of survey participants who reached a retention decision while in the program elected to remain in uniform, and 67 percent of these retained members reported that program participation "positively impacted their decision" to stay in the service.[45] This latter group represented 45 enlisted and 15 female officers in the program who elected to stay, translating to an estimated savings of $4.35 million to the Navy.[46]

Informal mentoring is the more traditional route, whether at work or at events like the "Women in the Air Force" Symposium mentioned in the *Air Force Diversity Strategic Roadmap* of 2010.[47] Low-cost mentoring opportunities include women-specific quarterly lunches or webinars with senior Air Force women leaders; webinars are already an avenue for certain development teams to convey data to their career fields, so the foundation is already in place. Finally, the Air Force could include training for senior officers who mentor junior officers of different

4346 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

races and genders. This training would not only address various approaches for interacting with and developing different personalities, genders, orientations, and cultures but also examine concerns that "those in the dominant group often fear that they will have to be politically correct, avoid giving critical feedback . . . [and] accept compromised performance."[48]

Regarding the third relevant priority of "retain[ing] a high-quality, talented and diverse total force," the service has taken concrete steps since the inaugural 2010 *Air Force Diversity Strategic Roadmap* to realize this goal.[49] Nevertheless, efforts to "achieve an inclusive environment that provides the total force with the opportunity to realize their full potential" should extend beyond surveys and tracking of quantitative performance measures.[50] It should also expand the Air Force culture to guarantee a well-rounded, mission-competent, diverse force, including a diverse senior leader cadre. The road map still contains too few measurable goals to indicate whether the Air Force is succeeding in this endeavor.[51] Indeed, as Steven Samuels and Dena Samuels point out,

> Even with the best of intentions, it is common to make surface-level, often cosmetic, changes in the hope of alleviating the problem. . . . Since leaders do not believe there is any underlying problem in situations like these, they see no need to make any underlying changes. Thus, they may release public statements pointing to successes they have accomplished in these domains, add a statement about being an equal-opportunity employer in their recruitment advertisements, or put women and people of color into their training films.[52]

The Air Force will stagnate in its diversity efforts without an in-depth review and overhaul of personnel policies and systems. Both the following recommendations and those mentioned above in the *Air Force Diversity Strategic Roadmap* indicate ways of making this document's aspirations a reality: policy transformation and program development leading to a stronger force.

4347 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Recommendations

Change Policy

Previous policy recommendations to mitigate issues concerning the retention of female officers include home basing, sabbatical programs, and a more flexible continuum of service (see the table below).[53] These recommendations, which remain valid, can be applied to a range of demographics, including men and women from the millennial generation, who tend to follow less linear career paths. However, the Air Force has not fully implemented these recommendations; they require action by the chief of staff of the Air Force and Congress. These programs would not only retain women but also promote key skill sets and cognitive diversity across the force.

Table. Reasons for leaving the Air Force (2002 data)

Reasons for Leaving the Air Force	*% Critical/Significant Factor*	*% Not a Factor*
Start a family	24	60
Stay home with children	27	61
Spend more time with family	41	40
Child care	8	80
Civilian jobs (more money)	12	67
Civilian jobs (more fulfilling work)	20	61
Civilian jobs (move ahead)	12	72
Civilian jobs (better cultural climate)	11	70
Geographic stability	41	42
Dissatisfied with Air Force leadership	27	42

Reprinted from Lt Col Laura A. H. DiSilverio, *Winning the Retention Wars: The Air Force, Women Officers, and the Need for Transformation*, Fairchild Paper (Maxwell AFB, AL: Air University Press, August 2003), 30.

4348 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The first proposed solution instituted home basing as an option, defined as "assigning a military member to the same base or location for an extended period of time."[54] In August 2001, the Government Accounting Office pointed out that more time between moves led to more likelihood of retention across the board—60–64 percent for three-plus-year tours as opposed to 46 percent for two-to-three-year tours (the average was two-year tours).[55] The Air Force slashed the number of moves in 2006 to conserve funds by keeping individuals on station for an average of four years (saving about $134 million annually).[56] An unimplemented proposal included more extensive home basing for officers—up to eight to 10 years. This initiative allowed junior officers "to develop roots in a community and a support network," minimizing the disruption of frequent moves.[57] Today a viable option entails expanding the current policy regarding permanent change of station, which allows selected enlisted members to volunteer for hard-to-fill spots via the Voluntary Stabilized Base Assignment Program for five years at a time.[58] For officers, a home-basing program is easier to implement in locations like Colorado Springs, San Antonio, or Washington, DC, because of the greater number of lateral and vertical openings. This initiative could retain individuals who otherwise would separate for reasons of geographic stability as well as reduce moving costs in this era of austerity. The AFPC would have to gauge the size of the program, but it could be lottery-based to keep the numbers at a manageable level and account for mission needs.

A second recommendation included a "non-punitive break in service option as a retention tool."[59] Earlier proposed, unimplemented solutions were a "one-year paid sabbatical" and a one-to-five-year unpaid break in service; each option would allow personnel to return as valued assets to the Air Force, saving training funds in the long run.[60] The National Defense Authorization Act (NDAA) of 2009 authorized each service to "carry out pilot programs under which officers and enlisted members of the regular components of the Armed Forces . . . may be inactivated from active duty in order to meet personal or professional needs and returned to active duty."[61] Congress authorized "20 officers

4349 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

and 20 enlisted members of each Armed Force" per year, for a maximum of three years.[62] In the 2012 NDAA, Congress extended the program to the end of calendar year 2015.[63] However, the Navy has been the only Department of Defense service to take advantage of the Career Intermission Pilot Program, a once-in-a career initiative that includes full health care and a small stipend for participants.[64] The Air Force should follow the Navy's lead in establishing a career-intermission pilot program of its own. It is within the secretary of the Air Force's power to establish this program; in the long run, it would not be overly expensive to implement. The Air Force could also examine the Coast Guard's temporary separation program, activated since fiscal year 2001.[65] That service rededicated support to the program in September 2012 as a "retention tool" and an option for personnel making life-changing decisions.[66] Although the Coast Guard falls under Title 14 and as such is not bound by NDAA restrictions, the Air Force could still benchmark from some practices. If well integrated, a break in service would not prove punitive to an individual's career. There is no reason why a program participant should not attain senior officer status since his or her "outside" experience could inject even more cognitive diversity.[67]

A third recommendation includes increasing the "permeability of [the] active-reserve barrier."[68] This kind of policy change is needed more than ever. The Air Force designed the 3-1 Integration Plan to allow the three components of the Air Force to combine their personnel systems, thus allowing for a true continuum of service, but it was shelved for reasons unknown to the author.[69] The fact that the Army initiated its continuum of service program in 2012, though, shows great promise. According to the *Army Reserve 2012 Posture Statement*, the goal is to "inspire Soldiers to a lifetime of military service, which includes seamless transitions between active and Reserve statuses."[70] If the plan unfolds as intended, a Soldier could take several paths, including a mix of reserve status and active-reserve.[71] It behooves the Air Force to track the outcome of the Army program and reconsider the shelved 3-1 Integration Plan.

4350 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Develop a Diverse Force

The Air Force should create solid development programs to inculcate diversity as a force multiplier; pursuing surface-level diversity can be counterproductive. If women and minorities are put into key positions based solely on gender or their minority status rather than on training or competence, they may be more likely to fail and either create or reinforce negative perceptions. Furthermore, these individuals would not receive the critical feedback they need to grow as leaders. Action plans should be sensitive to these factors and prepare leaders to develop their entire officer corps's core competencies so that, when chosen, everyone can step up confidently to leadership positions.

Intervention to inculcate diversity into the Air Force culture should be implemented incrementally. One approach to the 2013 *Air Force Diversity Strategic Roadmap*'s institutionalization priority involves linking diversity to mission effectiveness at every turn in the field. This reinforcement could be woven into opportunities found in mentoring, professional development sessions for officers, and wingman days. An initial focus, for example, would call for Airmen to uncover their own misperceptions or implicit biases about women officers (or minorities).[72] Free surveys are available, such as the Harvard Implicit Association Test, which measures subconscious biases via a simple online test.[73] Other activities could leverage case studies from free websites like the Stanford Graduate School of Business's "Leadership in Focus."[74] These programs could include a concerted effort to develop technical and leadership competencies in all Airmen.[75]

Conduct Surveys

The Air Force is on the right track with future survey topics, such as an upcoming one concerning women's reasons for leaving active duty.[76] However, this effort could expand to include crowdsourcing techniques. That is, instead of obtaining a snapshot of quantitative data, the Air Force could opt for a living source in which members provide reasons that women officers leave as well as possible solutions.

4351 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Not all reasons would be actionable, but the information would widen the aperture for senior leadership to develop better retention policies.

Additional data snapshots would also prove useful, such as expanding the 2013 *Air Force Diversity Strategic Roadmap*'s performance measurement of "track[ing] the number/percentage of supervisory total force personnel who indicate . . . they are serving as a mentor" to include questions about who they are mentoring and why.[77] The survey could include a hyperlink to mentoring resources. Another method for capturing the incorporation of diversity into the culture might entail using questions on diversity as it relates to mission effectiveness in unit climate-assessment surveys since current questions dealing with interrelationships tend to emphasize EO-related issues. The Air Force should also consider publicly tracking attrition rates of stressed career fields such as intelligence or cyber. At this time, the service publishes a thorough analysis of the attrition rates of pilots, navigators, and air battle managers only in its annual analysis of rated officer retention; it is difficult to understand why individuals are leaving if the numbers are not analyzed and published.

Use Avatars

The work started by the Squadron Officer College's use of avatars could grow to introduce diversity in a way that reaches the younger generation. Imagine a simulation in which an officer role-plays a minority or a woman via an online avatar, encountering some of the implicit biases or challenges. This will not necessarily change attitudes immediately but could plant some seeds of empathy. Another option with this technology would involve developing scenarios in which players encounter realistic, complex problems that can be solved only by a diverse virtual team.[78]

4352 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Conclusions and Areas for Future Research

This article has addressed the Air Force's recognition of diversity as a critical mission element and has expanded upon why and how divergence exists between policy and reality when it comes to the retention of women officers. First, many Air Force people do not consider diversity as a factor when they create operational teams or solve complex problems, no matter the findings of surveys regarding how Airmen recognize the importance of diversity.[79] Second, current personnel policies are not necessarily conducive to retention. The 2013 *Air Force Diversity Strategic Roadmap* recognizes this fact and has outlined actions to accommodate these values. Third, although the service has created groups to discuss diversity, programs that develop a diverse force are limited, especially in the education and mentoring fields. The Air Force should consider strategic-level tracks to close this gap in the retention of women officers—first, by pursuing policy changes at the Headquarters Air Force and congressional levels and second (and probably more time consuming and leadership intensive), by moving beyond rhetoric and a culture in which women-officer leaders are a normative part of achieving mission success.

Headquarters Air Force Global Diversity Division, charged with developing diversity policy and programs, is committed to resolving the aforementioned challenges. However, a small office of five permanent-party members is not enough to turn the tide of Air Force culture. Its personnel need assistance both from the service's senior leadership and from the field to create excitement about diversity.

Developing effective programs needs the most research and work. The objective is to move the Air Force beyond the guidance, talking points, and static websites, all of which operate via a pull versus a push methodology. Furthermore, it is not clear how the numerous speeches by senior leaders to niche audiences like the National Association for the Advancement of Colored People or Congress are translated to action. These programs should not only focus on those in the field but also reiterate the lessons at every educational opportunity,

4353 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

from accession programs to professional military education. Another area for further research, the introduction of leadership from the middle, would train a specific cadre of individuals on diversity to develop a peer cadre—much like the Air Force does now for resiliency.[80] Finally, as Samuels and Samuels recommend, "a framework is needed to help leaders become more culturally aware of other organizational members' experiences and needs . . . to highlight the manner in which the statuses of leaders might serve as blinders and even inhibitors to creating a diverse and inclusive workplace."[81]

Transforming culture is a difficult endeavor. Although the Air Force has taken great strides to initiate this change, it will require at least a generation of consistent involvement on the part of senior leadership as well as purposeful policies and programs to make diversity a true Air Force competency. The steps that the service takes in the next few years will make all the difference for the retention and development of diverse individuals. More important, however, is the goal of changing the attitude of the entire force to truly embrace diversity as a force multiplier in dealing with increasingly complex problems. ✪

10. MLDC, *From Representation to Inclusion*, 44.

11. Within the Air Force Academy, for example, the normative population is comprised of white Christian males. Anybody who does not fit into that category is not necessarily viewed as inherently belonging to that institution and often has to go above and beyond simply to justify his or her membership. Without conscious effort or education, dominant groups simply do not realize that others have a different experience or outlook than their own. As Steven Samuels and Dena Samuels remark, "When privilege is normalized, those in dominant positions tend not to see themselves as privileged and thus run the risk of ignoring their own role in perpetuating inequalities" or inadvertently "distance themselves from their goals." Steven M. Samuels and Dena R. Samuels, "Incorporating the Concept of Privilege into Policy and Practice," in *Attitudes Aren't Free: Thinking Deeply about Diversity in the US Armed Forces*, ed. James E. Parco and David Levy (Maxwell AFB, AL: Air University Press, February 2010), 326.

12. Lt Col Laura A. H. DiSilverio, *Winning the Retention Wars: The Air Force, Women Officers, and the Need for Transformation*, Fairchild Paper (Maxwell AFB, AL: Air University Press, August 2003), 36. In 2002 Lieutenant Colonel DiSilverio conducted a survey for her Air War College research paper that included this data. She observed that "the Air Force can focus its retention efforts on decreasing the conflict between having/caring for families and fulfilling military duties rather than on making the military look attractive in comparison to civilian opportunities. The Air Force has historically been focused on the latter" (ibid.).

13. This is not to say that women are promoted at the same rate. The MLDC made clear the existence of a gap, especially in the Coast Guard and Navy, due to any number of potential reasons. The latter include performance reports that are not competitively written and assignment matching. Promotion boards are not necessarily one of the reasons because they work under very clear direction regarding what is expected. MLDC, *From Representation to Inclusion*, 76–78.

14. With the millennial generation forming the junior officer ranks, monetary reasons are not necessarily incentives to stay. A 2011 survey of 250 junior officers (mostly Marines and Army and 86 percent male) noted that 75 percent of those surveyed claimed "personnel management issues" and that 57 percent cited "the limited ability to control their own careers" as reasons for leaving the military. Though only 4 percent of them were in the Air Force, the generational tendencies are probably similar. Sayce Falk and Sasha Rogers, "Ju-

4355 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

nior Military Officer Retention: Challenges & Opportunities" (master's thesis, John F. Kennedy School of Government, March 2011), 11, 53.

15. Philip Ewing, "Defense Leaders Fear Military-Civilian 'Disconnect,'" Politico.com, 20 February 2011, http://www.politico.com/news/stories/0211/49838.html.

16. Several examples exist in the civilian world, such as computer gamers who mapped the complex molecular structure of a retrovirus enzyme that perplexed trained scientists for years. University of Washington, "Gamers Succeed Where Scientists Fail: Molecular Structure of Retrovirus Enzyme Solved, Doors Open to New AIDS Drug Design," *ScienceDaily*, 19 September 2011, http://www.sciencedaily.com/releases/2011/09/110918144955.htm.

17. Scott E. Page, *The Difference: How the Power of Diversity Creates Better Groups, Firms, Schools, and Societies* (Princeton, NJ: Princeton University Press, 2007), xxv. For this article, cognitive diversity includes identity diversity. That is, the socialization of US society (especially the military) fits firmly into the masculine quadrant of any chart made by Geert Hofstede, Gert Jan Hofstede, and Michael Minkov. In a masculine society, male and female "emotional gender roles are clearly distinct"; masculine values such as work earnings and recognition are more esteemed than values found in feminine society, such as the importance of "relationships and quality of life." Due to this typical socialization in American society, women also tend to be cognitively diverse (they think differently) due to their identity diversity. Geert Hofstede, Gert Jan Hofstede, and Michael Minkov, *Cultures and Organizations: Software of the Mind* (New York: McGraw Hill, 2010), 140–41,151–52, 155. Alluding to organizational theorist I. D. Steiner, Dr. Scott Page notes that diversity is necessary for "*conjunctive tasks*, those in which everyone's contribution is critical" (emphasis in original). He also remarks that although identity diversity does not automatically translate to success, when it is linked to cognitive diversity and issues that require diverse thought, "identity diversity produces better outcomes indirectly." One could argue that this holds especially true in the case of the military since its leaders and many junior officers are tasked to resolve complex problems that need innovative solutions. Page, *Difference*, xv, xxv–xxvi, 13.

18. Credit Suisse Research, *Gender Diversity and Corporate Performance* (Zurich: Credit Suisse, August 2012), 12, 18, 19.

19. According to Frank Dobbin and Jiwook Jung, "The fact that board diversity has no effect on profits, but a negative effect on stock price, lends support to our thesis that institutional investors may sell the stock of firms that appoint women to their boards—not because profits suffer, but because they are biased against women." Frank Dobbin and Jiwook Jung, "Corporate Board Gender Diversity and Stock Performance: The Competence Gap or Institutional Investor Bias?," *North Carolina Law Review* 89, no. 3 (March 2011): 828, http://www.wjh.harvard.edu/~dobbin/cv/articles/2011_NCLR_Dobbin_Jung.pdf. The MLDC notes that "if it is not managed effectively, diversity . . . can actually reduce capability, most frequently through the decreased communication and/or increased conflict that result when some people are (or feel) excluded." MLDC, *Decision Paper no. 6: Diversity Leadership* (Arlington, VA: MLDC, February 2011), 6.

20. This topic should be considered for future research.

37. "Learning Philosophy," Princeton University Office of Human Resources, 21 June 2011, http://www.princeton.edu/hr/learning/philosophy/. From the Center for Creative Leadership, this model is "a research-based, time-tested guideline for developing managers [that] proposes engaging them with three clusters of experience, using a 70-20-10 ratio: challenging assignments (70%), developmental relationships (20%), and coursework and training (10%). Despite the popularity of the 70-20-10 rule, most organizations are still not systematic or intentional about using a synergistic combination of assignments-relationships-coursework to groom future leaders." Meena Surie Wilson et al., *Grooming Top Leaders: Cultural Perspectives from China, India, Singapore and the United States* (Greensboro, NC: Center for Creative Leadership, September 2011), 4, http://www.ccl.org/leadership/pdf/research/GroomingTopLeaders.pdf.

38. Dr. Fil J. Arenas (associate professor, Organizational Leadership Studies, Squadron Officer College), interviews by the author, 11 October 2012 and 14 December 2012.

39. Training and education are included as key parts of the development priority mentioned in the 2013 *Air Force Diversity Strategic Roadmap*. Work remains, despite the progress made in introducing diversity at various levels of accession and professional military education (PME) programs. Training and education should go beyond these efforts and should be emphasized at every opportunity to link with mission needs. Increasing awareness and influencing attitudes vis-à-vis diversity starts with officer accession programs. Solid efforts have begun at the Jeanne M. Holm Center for Officer Accessions and Citizen Development, which oversees all officer accession programs with the exception of those at the United States Air Force Academy (USAFA). The Holm Center introduces the diversity concept to its cadets and officer trainees, specifically via a two-hour lesson entitled "Managing Diversity," which utilizes team-building exercises to cover the elements and challenges of leading a diverse force. The USAFA has been most holistic and dedicated in its approach to diversity. Though the academy's focus remains on accessing a more diverse force, it has recognized the need to develop solid action plans not only to diversify its teaching cadre but also to train it, expand opportunities for retention, and put resources behind its efforts. Of the three main Air Force officer PME programs, the one geared toward junior officers (Squadron Officer School) has the most developed program to comply with the Air Staff's direction. A 50-minute in-class course introduces the Air Force's emphasis on diversity, and a 90-minute team-building exercise touches on diversity as a consideration for building a team. The Air Command and Staff College, geared toward majors, has some diversity elements in its curricula, including an elective historical survey of women in the military; however, only 12 of 485 students were enrolled in this particular course. At this time, the Air War College does not have any topics on diversity in its curricula. Nevertheless, the Leadership Department is looking into ways to interweave diversity into its Joint Strategic Leadership course as well as its 360 leadership survey for Annual Year 2014's class; this effort would include administrating the Harvard Implicit Bias test. See Air Force Global Diversity Division, *Air Force Diversity Strategic Roadmap* (2013), 14; Dr. Charles Nath III (director of curriculum, Holm Center), interview by the author, 19 October 2012; *USAFA Diversity Plan* (Colorado Springs, CO: USAFA Diversity Office, June 2009), 2–3, 14, http://www.usafa.edu/superintendent/diversityoffice/links/AFD-110316-012.pdf; Arenas, interview, 11 October 2012; Dr. Mary N. Hampton (associate dean for academics, Air Command and Staff College / DEA), interview by the author, 1 November 2012; and COL Gene Kamena, USAF, retired (former deputy department

75. Part of developing competency is ensuring that leaders are gender-neutral when it comes to selecting individuals for certain positions. One finds a powerful example of this principle enjoying success in the civilian world. For several decades now, orchestra audition panels have gone to great lengths to overcome gender bias. Panels considering future players will do so without initially seeing the candidates. They will go to such lengths as having men escort women candidates so that the candidate sounds like a man walking. Having leveled the playing field, the panel focuses solely on the quality of the music. According to the study, "Estimates based on the roster sample indicate that blind auditions may account for 25 percent of the increase in the percentage of orchestra musicians who are female." Claudia Goldin and Cecilia Rouse, "Orchestrating Impartiality: The Impact of 'Blind' Auditions on Female Musicians," *American Economic Review* 90, no. 4 (September 2000): 715–41.

Col Suzanne M. Streeter, USAF

Colonel Streeter (USAFA; MA, Middlebury College; MA, Naval Postgraduate School; MA, Air University) is currently assigned to the US Cyber Command Joint Intelligence Operations Center as the division chief of Intelligence Plans and Exercises. This division serves as the driving force behind intelligence planning support to deliberate and real-world contingency planning of cyber operations. Colonel Streeter is a master intelligence officer with 18 years of operational intelligence experience at all levels of the Air Force, including staff experience at Headquarters Air Force. She was most recently a student at the Air War College. Previously, she was deputy commander of the 548th Intelligence, Surveillance, and Reconnaissance Group, Beale AFB, California, which included 1,200 Airmen and civilian personnel engaged in the rapid processing, analysis, fusion, and reporting of intelligence information collected by U-2, RQ-4, MC-12, MQ-1, and MQ-9 reconnaissance aircraft supporting tactical military forces, regional commanders, and national priorities worldwide. She has also been a director of operations and squadron commander. Deployments include translator for Operation Decisive Endeavor, officer in charge of the Cryptologic Services Group at the combined air and space operations center, and officer in charge of setting up the Air Force's first in-country expeditionary intelligence-exploitation squadron in support of Operation Enduring Freedom.

4363 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

F-117 in the Gulf War, the program placed high emphasis on the utility of low radar observability. Designed to provide combat aircraft for the Air Force, Navy, and Marine Corps as well as a host of allies worldwide, the Joint Strike Fighter (JSF) would usher in a revolutionary improvement in American airpower.

Instead, the program has been troubled, characterized by the Pentagon's acquisition chief as "acquisition malpractice," and finds itself well behind schedule and over budget.[1] Rather than an affordable, capable fighter aircraft, operational in large numbers by 2015, the F-35 continues to arrive late and cost more than anticipated.[2] Program delays, unmet performance requirements, and spiraling costs have recently run full tilt into an austere budgetary environment dictated by the Budget Control Act of 2011.[3] More significantly, the program emerged from decades of North Atlantic Treaty Organization (NATO)–centric Cold War experience; furthermore, the Air Force did not envision it either for the Pacific theater or for an adversary with China's air defense capabilities. In this light and despite more than a decade of development invested in the program, budgetary realities should serve as an impetus to reexamine the Air Force's participation in the F-35 program and the future of the fighter force.

We have choices—if we are willing to entertain them. The Army's treatment of the Comanche program offers an example of a bold move in aviation that allowed that service to both modernize and recapitalize. This example shows a potential way forward and should remind Airmen that the Air Force is essential for national security, that no individual aircraft has ever proven indispensable to national security, and that we should be wary of risking national airpower capabilities in our pursuit of a single type of platform. This article presents an alternative future structure designed to preserve the combat air forces (CAF) as an agile and combat-ready multipurpose force, restoring the "high-low" mix that the Air Force essentially abandoned in the 1990s.[4] It offers a future force, called here the "alternate force"—one more broadly capable and affordable than the force that the current path will produce.

4364 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The Comanche

At the heart of any JSF discussion lies the belief that the program cannot be cancelled—that any attempt is doomed to failure because of the spread of the program structure in the United States and internationally. Despite any great unwillingness to end the program, doing so is certainly not impossible. Clearly, the Army's experience with the Comanche is instructive.

In 2004 the RAH-66 Comanche had been in development for 22 years, most of that time as a major defense acquisition program. Two prototypes had been built, and the program was healthy. Yet, the Army terminated it due to questionable utility, expected unaffordability, and the presence of a credible alternative. Acting secretary of the Army Les Brownlee, along with Gen Peter Schoomaker, the Army chief of staff, announced the termination, explaining that

> we've examined closely our resourcing plans for aviation and concluded that some of the capabilities those funds would provide are no longer consistent with the changed operational environment. Therefore, General Schoomaker and I have recommended that the Comanche helicopter program be terminated and those resources reallocated to restructuring and revitalizing Army aviation. With the approval of the president and the Secretary of Defense, we began briefing key members of Congress this morning.[5]

Key to the arrangement that terminated the Comanche was repurposing of the programmed money entirely into Army aviation with Joint Staff and congressional consent. Today, the average age of the Army's rotary wing fleet is less than it was in 2004, the AH-64E is poised for the production line, the Army flies remotely piloted vehicles that it did not possess eight years ago, and the rotary transport fleet has been largely recapitalized—even in the Army Guard. In 2004 the Army courageously euthanized the program, and, despite fighting two wars in that time frame, its aviation arm benefited more than one would have expected had the Comanche continued in 2004.[6] The Army managed the termination so astutely that it became a nonevent,

4365 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

both politically and financially. Redirected into other Army aviation programs, the money largely went to the same contractors in the same districts that would have received the Comanche funding.

Admittedly, the parallels go only so far. The JSF program, which is much larger and currently produces aircraft, involves a number of international partners who have invested in the program at varying levels. However, the rationale for terminating the F-35 programming to allow a redesign of the tactical air (TACAIR) enterprise remains the same: s*ome of the capabilities those funds would provide are no longer consistent with the changed operational environment, and it does not serve either the United States or our partner nations to continue on the current path*.

The Challenges

Even if funding were unlimited, reasons might still exist for terminating the F-35. Specifically, its performance has not met initial requirements, its payload is low, its range is short, and espionage efforts by the People's Republic of China (PRC) may have compromised the aircraft long in advance of its introduction.[7] Our assumptions about the operational environment, made more than a decade ago, do not match current reality with respect to either the threat (worse) or the potential adversaries (more diverse). The mission of the aircraft—to penetrate the most advanced air defenses and drop precision-guided munitions on critical targets of a peer adversary—remains questionable at best, especially if that peer is located in the Indo-Asia-Pacific region, where basing is limited, ranges are long, and potential adversaries have logistical advantages. Despite official pronouncements in support of the F-35 program, the Air Force must remember that its contribution to the nation is fundamentally more about *airpower* than about any particular aircraft. In a resource-constrained environment, commitment to the F-35 must be considered secondary in importance to the joint requirement for TACAIR.

4366 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

A number of related challenges are associated with the future of the CAF. These problems are not limited to insufficient training resources; rather, they derive from a force-structure shrinkage that has continued for two decades. Financial imperatives that led to a force-structure drawdown in the first place have not gone away, leaving us with a number of critical hurdles to clear before the end of the decade:

1. The Air Force's capability for suppression of enemy air defenses (SEAD) has dwindled in the almost 20 years since retirement of the EF-111A and F-4G. The Air Force has not replaced either the aircraft or, critically, the trained aircrews (unlike the Navy, which has a growing force of EA-18G Growlers). The F-22, F-35, and B-2 are shorn of support capabilities that might enhance their effectiveness and must rely on Navy support.
2. The Air Force possesses no affordable, deployable light attack / armed reconnaissance capability that it can use for irregular warfare. Particularly limiting is the fact that, with the sole exception of the A-10, the service has no capability to operate fighter/attack aircraft from airfields that are too short or rough to handle fast jets. This liability has become a problem of global reach in that the Air Force cannot provide persistent air cover with TACAIR to large portions of the globe, even with tanker support. Without a carrier air wing available to provide short-term coverage, there are few remaining options for CAF support to far-flung forces. Had the Soviets not built large airfields in both Iraq and Afghanistan, we might have faced this problem a decade ago.
3. Basing opportunities are limited, and the vast majority of airfields worldwide remain incapable of supporting legacy or future fighters. The Air Force is neither prepared nor equipped to operate small force packages from very austere bases by using thin logistical pipelines and relying on local support. Distributing single squadrons of easily supportable aircraft over multiple airfields could well deliver a very effective combat capability difficult to counter, particularly in South America, Africa, and the Pacific. In

4367 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

the Asia-Pacific, the ability to operate from fields 6,000 feet long more than doubles the potential basing and provides opportunities on island bases that cannot accommodate a longer strip.

4. The lack of absorbable cockpits has already drawn the Air Force's inventory of fighter aviators to a point where demand exceeds inventory and is projected to do so well past 2024. Even this date may be a product of the width of the chart and not the result of a plan to make the demand and inventory lines congruent again. Without a rapid infusion of hardware and an increase in the pilot-training pipeline, we will not have the fighter/attack aviators necessary to fill the squadrons and carry out all of the associated tasks, including conducting tests, training pilots, attending professional military education institutions, and filling the rated staff.[8]
5. The Air Force has no practical ability to supply combat aircraft to the air forces of partner nations that cannot afford the F-16—a deficiency that poses particular difficulties in building or rebuilding such air forces, particularly in Asia and Africa. The significant obstacle of procuring light air support aircraft for the Afghan Air Force will be further compounded by the lack of tactics manuals; established tactics, techniques, and procedures; or experienced aircrews to train Afghan pilots.
6. The Air Force has spent significant time and effort over the last 10 years improving both its own ability and that of our NATO partners with respect to close air support (CAS). Given a shrinking pool of ground attack aircraft and the increasing cost to operate them, the service already has insufficient sorties available to support CAS training for joint terminal attack controllers.
7. Regarding homeland defense, no armed platform occupies a niche between Customs and Border Patrol / Coast Guard helicopters and fast jets, posing a mismatch of capabilities any time we need to intercept slow-moving aircraft.

4368 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

8. The use of costly, aging F-15 and F-16 aircraft for air sovereignty alert (ASA) roles remains an expensive overmatch in capabilities that a modern, less expensive airframe could relieve. This challenge is particularly acute for the Air National Guard, which has faced continuous loss of frontline combat capability as legacy fighters and A-10s are removed from the force.

Commitment to the F-35 makes every one of these issues worse, not only because the aircraft itself will not fill these gaps but also because the required funding effectively deprives the Air Force of the resources demanded to address them. At the heart of the disconnect lie two decades of vision that emphasizes the "all-fifth-generation" fighter force that consists solely of advanced low-observable fighter aircraft.[9] This approach, which concentrates a notional future conflict against a peer adversary, relies heavily on the assumption that a fighter force designed for the most intense conflicts is automatically suitable for any contingency. The pursuit of this vision comes at a very high opportunity cost and invites a great deal of risk, both programmatic and operational.

Evaluating the Need for a Course Change

Pursuit of the full F-35 buy of 1,763 aircraft remains the articulated Air Force strategy—a plan that inflicts significant damage on the existing TACAIR fleet. Putting aside the impending loss of the newly upgraded A-10, the service has been engaging in an unprecedented force-structure drawdown throughout the total force, reducing fighter and attack strength across the board. In 2013, 17 fighter squadrons were grounded for lack of flying hours while the Air Force simultaneously attempted to increase the production rate of the F-35.[10] The drive for large numbers of increasingly expensive F-35s has taken its toll on flying hours and upgrades for both the legacy fleet and the F-22. Hours for fighter aviators are roughly half of what they were in the Gulf War, placing the service's aircrews in the unenviable position of flying less than the Chinese and some European allies.[11]

4369 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The "fighter redux" has severely affected the inventory of the Air National Guard and Air Force Reserve, with some fighter and attack units transitioning from the A-10/F-16 to airlift or remotely piloted aircraft and others losing their flying roles entirely.[12] Although it garners short-term savings, this approach alters the role of the Air Reserve Component (ARC) as a strategic reserve and as a second chance to "capture" active duty aviators and maintainers who are leaving the regular Air Force. The ARC should be postured to regain a broad spectrum of aviation capabilities, reequip for the ASA mission, and capitalize on existing locations in proximity to Army and Marine Corps bases and training areas. A recapitalized ARC would include the full range of capabilities from the upgraded fourth-generation fighters through the OA-X and FT-X.[13]

Even a reduced buy of F-35s is problematic because of the high cost of supporting a JSF fleet of any size, given the doubling of unit costs since 2001.[14] The test program for the aircraft remains about one-third complete, leaving the Air Force with quite limited visibility into the platform's actual costs and capabilities. At this writing, the aircraft has only recently employed its first weapons on a test range. In many respects, the F-35 is a difficult aircraft to argue against because its potential remains largely unknown and discussions tend to address what the aircraft "can" do despite the absence of operational test data that actually determines how an aircraft performs. In this context, what the aircraft "should" be able to do or "might" accomplish is treated as established fact despite the lack of either testing or verification.

The Air Force has proven consistent in the pursuit of "fifth generation" fighters as an essential war-fighting requirement. One of the key shortcomings of this presumption is that it is largely "faith-based" in two respects. Firstly, despite the history of the F-35 program, it presumes that the capabilities we expect will be delivered. Secondly, it is based on a belief that radar low observability will remain effective against future air defense threats. Notably, that presumption of stealthiness rests on shaky ground. Although true for the F-117 against Iraq's

4370 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Kari system in 1991, stealthiness is unlikely to remain so against an adversary that has two decades to prepare for US stealth fighters, which have much higher infrared, visual, and emitter signatures than did the F-117.[15] Only eight years later, the latter aircraft proved vulnerable to a surface-to-air-missile system that had reached initial operational capability in 1959, and we should not presume that Russian and Chinese radar developers have wasted the intervening decades since the Gulf War.

The argument for the F-35 rests heavily on a threat environment that is far from global. In reality only Russia and China can pose the kind of antiaccess, area denial (A2AD) environment that justifies a massive investment in stealth. Air Force leadership is rightly considering other possible adversary capabilities of the future, but in reality only one operator of a true stealth fighter exists—and that is the US Air Force.[16] That service has remained the sole operator of stealth fighters since the late 1980s. Even a decade from now, the F-22 inventory alone will likely outnumber all other models of foreign fifth-generation fighters combined.

The Air Force has not lost a plane to a hostile aircraft since the Vietnam War. The ground-based air defense threat has advanced significantly in the past two decades, but even though some extremely capable systems are available to potential adversaries, the number of nations able to purchase and operate them is quite limited. Outside China and Russia, no massive threat from an advanced integrated air defense system exists. Moreover, China is a poor example of a threat to cite if someone is trying to justify a short-ranged fighter with limited payload flown from island bases within range of overwhelming missile attack.

These facts make the risk calculation involved with prioritizing stealth over performance, range, and weapons loadout inherently suspect—and the F-35 might well be the first modern fighter to have substantially less performance than its predecessors. Admittedly, the classified status of many of its capabilities prevents full disclosure or public debate regarding this point. However, if we prioritize radar low observability as the primary consideration at the cost of many other at-

4371 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

tributes necessary in a fighter, the stealth-based paths become stealth-limited paths. This priority may indeed sacrifice readiness, force size, magazine depth (ammunition supply), and other force structure to build and maintain a fleet of aircraft that has limited utility against the majority of TACAIR challenges worldwide, not to mention questionable capability in the A2AD environment of the Western Pacific.

A strategy based on the presumed ability to penetrate advanced air defenses is viable only if it does not prevent the pursuit of other strategies. If the force design is instead a niche capability usable only against certain adversaries under favorable conditions and only if that strategy is pursued, then we have significantly reduced our flexibility and have taken immediate airpower options off the table for the promise of a single new capability that is still more than a decade away. Pursuit of an expensive, modern, cutting-edge force has already cost us in terms of force size, structure, flying hours, and entire areas of expertise that we no longer have. In its quest of the F-22 and now the F-35, the Air Force has traded away its dedicated electronic warfare (EW) fighters, the training programs that supported them, and the EW-savvy crews who manned them, leaving fighter EW the purview of the Navy and Marine Corps. In light of the A-10's impending retirement, CAS is primed to go the same way as EW.

The Alternative

It is easy to criticize a developmental program; in fact, all advanced fighter programs endure robust criticism throughout their developmental lives. The strengths of any particular criticism are irrelevant in the absence of a genuine alternative. Unwillingness to investigate an alternative is not the same as not having one. The alternate force postulated here represents an attempt to illustrate that alternatives not only exist but also may present a more robust defense for the nation and its interests.

4372 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The fundamental objective of this force structure construct involves making a trade-off between a TACAIR force of limited numbers and narrow depth for a larger, more broadly useful one designed to tackle all of the Air Force's institutional challenges highlighted above. It does not entirely eliminate the F-35 force, given that we already have more of them than we ever had F-117s, but it effectively terminates the Air Force's participation in the program after fiscal year (FY) 2014. The objectives of this proposal are to

- maintain a limited number of F-35As (those already purchased) as a replacement for the capabilities lost upon retirement of the F-117;
- create a modernized TACAIR fleet consisting of a high-low mix of modernized legacy fighters, light attack aircraft, and multipurpose jet trainer / attack aircraft;
- recover some "sunk cost" of the F-35 program by using advanced systems to modernize older fighters, in effect fielding fifth-generation systems in fourth-generation airframes;
- restore the Air Force's SEAD/EW fighters and crews;
- expand the service's global reach capabilities by providing deployable TACAIR assets that can operate from short, rough airstrips on a logistical shoestring;
- increase the number of absorbable cockpits to the point where the Air Force can augment the inventory of fighter/attack aviators to meet requirements;
- invest in affordable, exportable "light combat aircraft" derived from Air Education and Training Command's T-X program;
- allow the Air Guard to maintain its position as the operational reserve and "relief valve" for experienced fighter/attack aviators while recapitalizing its portion of the CAF; and
- build a TACAIR force that can meet the nation's demands for airpower capabilities even in the face of increasing fuel costs and decreasing budgets.

4373 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

This force design effectively captures sensors and systems intended for the F-35 and places them into new-build and refitted F-16s and F-15Es. To a great extent, this process is already occurring but without full funding. Such a realignment of future force structure terminates the F-35 in favor of advanced fourth-generation fighters, electing to defer stealth to a later generation. It involves a strong investment in improved fourth-generation aircraft, retains the A-10, and adds hundreds of OA-X, FT-X, and AT-X platforms.

Certain assumptions about the global context are necessary:

1. The most capable potential adversary remains the PRC with Iran and the Democratic People's Republic of Korea (DPRK) posing challenges of their own.
2. No significant change occurs in overseas permanent basing.
3. Air Force funding drops to sequester levels until at least 2024.
4. The PRC maintains its current spending levels and development of both combat aviation and theater ballistic missiles. No fundamental change occurs in governance of the PRC, Islamic Republic of Iran, or DPRK.
5. Continuous fighter presence remains a requirement in US Central Command's and/or US Africa Command's area of responsibility.
6. The existing B-2 and B-52 force is unaltered.
7. Fuel costs continue to increase.[17]

The force design reflects the reality that since Vietnam, the United States has been involved in far more irregular-style conflicts than regular ones—but that giving up a force designed to achieve coercive effects against a peer adversary amounts to an unwarranted risk. It expands upon the high-low mix model that gave us the F-16 and F-15 and builds a high-medium-low mix of TACAIR capabilities.[18]

4374 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Force Design

The existing F-22 fleet anchors the "high" end of the TACAIR mix. One oversize F-35 wing, modeled on the 37th Tactical Fighter Wing at Tonopah Test Range, Nevada, will fill the stealth fighter gap left by the F-117. The bulk of the high end will consist of upgraded F-15C, F-15E, and F-16C/D/F aircraft. Many of the upgrades to the fourth-generation fleet will be "harvested" from the JSF program, whereby advanced subsystems from the F-35/F-22 that are ready for fielding will be retrofitted into older fighter designs. In effect, this process is already happening with the F-15E and F-15C to some extent; upgrades of sensors and EW gear should be spread as far as possible throughout the force, including the B-52, not otherwise addressed by this article. The Air Force should purchase a limited number of new aircraft, with 60 F-15Gs and 72 two-seat Block 70 F-16Fs as the baseline. Such purchases are only partially additive. The Block 70 squadrons will be an in-place upgrade of Block 40 squadrons while the F-15G Strike Weasels are added to the force to replace the long-lost F-4G/EF-111A and the critical expertise that came with them.[19] When economically feasible, existing fourth-generation airframes with significant service life remaining should be upgraded to a common standard.

The middle of the TACAIR mix will include the A-10 and combat variants of the T-X—the FT-X and AT-X. The A-10 is facing its own fatigue problems, and the introduction of the OA-X (see below) may allow the Air Force to reduce the A-10 inventory to a number that can credibly support operations on the Korean Peninsula. The service should procure the F-X, envisioned as a T-38 replacement, in three variants. The base airframe—T-X, essentially a modernized T-38 equivalent purchased off the shelf—would constitute the most numerous aircraft (400). The AT-X would take the form of an all-weather, combat-capable, multirole T-X with air-to-ground capability including guns, rockets, and precision-guided munitions. The FT-X would be a fully capable light fighter with a modern air-intercept radar and air-to-air-missile capability comparable to that of the F-16C. The FT-X is intended as a good fit for the Air

4375 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

National Guard's ASA mission and for use as an aggressor. As such it might replace the Guard's F-16s that have reached the end of their service lives. Both aircraft would also serve as relatively low-cost, dual-role, exportable fighters/trainers (similar to the F-5A/E). The low end of the manned TACAIR spectrum is occupied by the OA-X, Air Combat Command's concept of a modern turboprop light attack aircraft—intended to be additive over and above existing TACAIR numbers except when A-10 units are upgraded directly. The OA-X will assume the burden of irregular warfare and counterterrorism deployments as well as provide ASA alert on demand.[20]

The following offers a quick look at the future CAF without the JSF. In April of last year, members of Headquarters US Air Force / A8 ran a series of cost projections to 2023, using a tradespace analysis tool against the expected funding of the service's air superiority (AS) and global persistent attack (GPA) portfolios.[21] This reality-based assessment used a budget baseline that locked in spending levels expected from the Budget Control Act of 2011, with a real defense budget growth of a paltry 0.3 percent. All F-35 procurement funds from FY 2014 to FY 2023 were redirected within the AS and GPA portfolios, which do not include the MQ-9, B-52, or B-2 aircraft.[22] F-35 research, development, test, and evaluation funds are left intact for systems migration and maintenance of the aircraft already purchased although doing so will never be cost effective. The "sand charts" supporting this plan include sustainment as well as procurement costs. Table 1 reflects the recapitalized fighter/attack (plus B-1) total active inventory (TAI). The last two columns represent an increase in aircraft and cockpits compared to the FY 2013 programmed force extended (PFE) (1,763 F-35s). In some respects, this comparison is unfair. That is, the FY 2013 PFE overshoots the projected budget line (particularly beyond five years) by 10s of billions of dollars even before sequester while this alternate force stays within the sequester limits, with no gimmicks such as expected efficiency improvements or transfers from other portfolios.

4376 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Table 1. Alternate fighter/attack aircraft, TAI 2023

Mission Design Series	*Source*	*Regular AF*	*ARC*	*Total*	*Aircraft Delta*	*Cockpit Delta*
F-22	Existing	167	20	187	0	0
F-35	Existing	56	0	56	0	0
F-15C/D	Upgraded[a]	113	116	233	-16	-16
F-15E	Upgraded[b]	218	0	218	0	0
F-15G[c]	New Build[d]	60	0	60	+ 60	+120
F-16C/D	Upgraded[e]	377	361	738	-282	-282
F-16F	New Build[f]	54	18	72	+72	+144
AT-X	New Build	38	18	56	+56	+112
A-10C	Existing	60	90	150	-133	-133
FT-X	New Build	36	58	94	+94	+188
OA-X	New Build	132	108	240	+240	+480
Total Fighter/ Attack		1,311	789	2,100	+91	+613

[a] F-15C/D upgrades included infrared search and track, active electronically scanned array radars (APG-63v3), and the Eagle passive/active warning and survivability system (EPAWSS) upgrade to EW systems.

[b] F-15E upgrades included APG-82 and EPAWSS.

[c] The F-15G (called EF-15E by Boeing) moves the EW systems from the EA-18G to the F-15E+.

[d] New-build aircraft were priced for both purchase and operation and maintenance in accordance with existing examples. F-15Gs were priced at $110 million each, with the F-16F at $70 million. The baseline for the AT-X was the Royal Air Force's Hawk T2, priced at $33 million in adjusted dollars; the FT-X was priced at $35 million. The OA-X was priced at the light attack / armed reconnaissance + 20 percent price at $12 million each.

[e] F-16C/D upgrades, which were largely applied to Block 40/42/50/52 aircraft, consist of the combat avionics programmed extension suite radar / EW upgrade plus a service-life extension.

[f] The F-16F is a Block 70 F-16 modeled after the Israel Defense Force's two-seat, medium-range F-16I Sufa.

Under this projection, the fighter/attack force in 2023 includes 2,100 TAI aircraft, 91 more than the unconstrained PFE, with a concurrent increase in cockpits because every new aircraft is a two-seater.[23] Table 1 does not account for all of the money spent; B-1Bs were reduced (table 2).

4377 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Table 2. Alternate bomber aircraft, TAI 2013

Mission Design Series	*Source*	*Regular AF*	*ARC*	*Total*	*Aircraft Delta*	*Cockpit Delta*
B-1B	Existing	20	0	20	-18	-72

By 2023 the complete plan divests 18 B-1Bs, A-10s that have not already been rewinged, and the oldest F-16s in favor of 540 brand-new F-15Gs, F-16Fs, OA-Xs, AT-Xs, and FT-Xs. The Air Force's long-dormant EW fighters return, reducing dependence on the short-range EA-18G. Included in the reallocation are the entire GPA/AS sequester bill and munitions funding to 80 percent of desired war reserve as well as legacy modernization and upgrade. No training or range funds were raided. In the target year, production lines for the light combat aircraft (OA-X, FT-X, and AT-X) remain open, allowing for future purchases after the "bow wave" of expenditures subsides and for development of the long range strike bomber as well as the sixth-generation F-X. An alternative not only exists but also restores long-dormant capabilities and increases the size of the force.

Strategic Risk Management

The viability of the alternate force cannot be divorced from a discussion of force structure, which itself addresses expectations for twenty-first-century airpower. It is reasonable to assume that any conflict which involves the joint force also involves airpower application; consequently, we should give careful thought to what airpower brings to the fight.

Categorizing potential conflicts as "most likely" through "most threatening" and then making the case that the most threatening is of primary importance has become habitual. For the wars in Iraq and Afghanistan, the Air Force followed this approach—one that had the unfortunate effect of placing a heavy burden on legacy jet fighters that used only a fraction of their capabilities in these two wars. The ser-

4378 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

vice's preferred structure emphasizes the most threatening conflict—often the descriptor for major combat operations with the established military forces of a peer or peer-like state.

The fifth-generation fighter is held up as a hedge against the most threatening scenario, as if we must use this particular aircraft to fight a peer nation. This attitude is typical of a cultural belief that superior technology will lead to American victory and that if we lack the most technologically advanced aircraft, we cannot prevail in war. This hardware-based, strategy-independent assumption fails to consider the possibilities inherent in an approach that encompasses a broad range of airpower capabilities in favor of a very specific niche capability. It is also demonstrably false. Clearly, we had a technological edge in Vietnam, rough parity in Korea, and, arguably, technological inferiority against the Luftwaffe. Yet, the outcomes of those conflicts did not align with the associated aircraft technological advantage.

Under the approach that has prevailed since 2001, any possible conflict other than the most threatening one is a lesser-included case that a stealthy niche force can handle effectively. In effect, the F-35 in particular is presented as having broad applicability that makes it inherently well suited to any form of conflict simply because it can handle the so-called high end, when in reality the data does not support this conclusion. Using Afghanistan as an example, we simply could not have afforded to deploy or employ F-35s in the fashion that we employed F-16s and F-15Es—based on the operation and maintenance (O&M) costs or the fuel consumption, to say nothing of the decremented airframe life.[24] The use of existing fourth-generation aircraft in Iraq and Afghanistan was itself far more costly than a comparable strategy pursued with modern light attack aircraft, making the "lesser included case" path very hard on equipment, logistics, and personnel.[25]

Realistically, irregular conflicts are the most likely to occur, given that this has been the case throughout recorded Western military history.[26] Withdrawal from Iraq and eventual withdrawal from Afghanistan will not presage the end of US involvement in irregular warfare.

4379 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

America is currently involved in Mali, the Philippines, Afghanistan, Pakistan, Yemen, Jordan, Uganda, and the Horn of Africa; Libya is a fading memory; and Syria remains a possibility. A very fuzzy dividing line also exists—a conflict with China over Taiwan might not prove most threatening to the United States if it remained a conventional battle. Further, a collection of irregular challenges might very well aggregate to provide a most threatening scenario, especially if it involved the collapse of a nuclear state or loss of access to critical resources, territory, or aspects of the global commons.

Making the "lesser-included" argument particularly weak is the assumption that forces constructed for a less intense, broader challenge are inherently inferior. Capabilities such as endurance, ordnance diversity, weapons payload, maneuverability, fuel economy, range, and rough field capability are not considered worthwhile in the face of a binary classification—stealthy / not stealthy. The environment in which a conflict occurs is one of the defining aspects of any war, unquestionably having an impact on the flavor of airpower capabilities that can be brought to bear. If all environments, strategies, and adversaries are lesser-included cases of the "stealth only" option, then large numbers of F-35s would make sense—if they are affordable. However, if that is not true, then we ignore the consequences of being unable to fight proliferating and widespread "most likely" scenarios—or the obvious consequences of treating irregular warfare challenges as a lesser-included case and flying the wings off our fast-jet TACAIR, despite a decade of hard data on the effect of this approach.

The all-fifth-generation force also ignores the wide applicability and deterrence value of having a flexible force that can do more than one thing well, particularly under uncertain conditions in a rapidly developing crisis. There is always value in deploying combat aviation forward if we can accept the risk. Such risk has nothing to do with an aircraft's stealthiness but everything to do with how fast we can deploy airpower into austere conditions, with limited manpower, to conduct combat operations shorn of a fixed, preplanned basing structure. It

4380 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

would be a much easier decision to deploy OA-Xs or AT-Xs into Ukraine today, even knowing that we risked their loss on the ground, than to accomplish the same task with F-35s. If US Air Forces in Europe currently possessed light combat aircraft (OA-Xs, AT-Xs, and FT-Xs) capable of operating on a logistical shoestring from Ukrainian airfields in poor condition, then the supreme allied commander, Europe, would no doubt sleep more soundly in the face of a Russian irregular threat—which by itself was enough to secure Crimea.

The battle between the most threatening and most likely scenarios leads to an infertile discussion of false trade-offs. The force structure built solely for the most threatening scenario is fundamentally flawed because it relies on a false assumption that the A2AD challenge can be mitigated solely by fifth-generation fighters—in particular, a short-range, long-runway fleet shorn of EW/SEAD support. A force structure that discards some tailored capability for most likely conflicts may be unable to meet the needs of the nation because it relies on a faulty assumption that such a force cannot provide coercive effects against a peer and is therefore of little value.[27] Both of these scenarios ignore basic lessons in the art of war. If we have more employment options from more places, then we have more opportunities to gain leverage against an enemy. If we intentionally minimize our list of possible options, then we allow our adversaries the luxury of building and training a force designed to counter a limited US Air Force.

End State

The broad approach taken in the design of this proposed alternate force results in an increase in the number of fighter/attack squadrons and a significant increase in the number of absorbable cockpits while reducing O&M costs over the PFE.[28] It recognizes that one of the primary drivers of readiness problems is the high rotational burden on the fast-jet fleet and creates a force structure that drives the vast majority of the rotational burden to the lowest-cost aircraft with the lowest O&M and lowest fuel consumption. The approach also backs up the global-

4381 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

reach tenet with aircraft that can fight from unimproved airstrips. The capability to counter advanced air defenses is retained, but it returns to an approach proven in Vietnam and Operation Desert Storm—specialized aircraft with well-trained crews flying dedicated missions in support of strike aircraft. The current Air Force approach, which has relied entirely on the Navy for jamming support for 16 years, is reversed with a combined Weasel/Jammer capability in the F-15G. The F-35s already purchased are retained, and advanced capabilities will be available to satisfy commitments made to partner nations.

Collateral effects include the shifting of the burden of expensive low-observable fighter programs to the PRC, which cannot effectively use them to project power far beyond the mainland. Although none of the aircraft numbers lost in the fighter reductions of the last decade are regained, the average age of the fleet is slightly reduced. Inclusion of the F-16F adds a medium-range F-16 variant better suited to the Pacific theater. Adding combat aircraft types that are less expensive than the heavier fighters better positions the Air Force to engage effectively with emerging partner air forces, expanding our influence and opening up opportunities for burden sharing. Critically, with most purchases complete in 2023, it frees multiple billions of dollars for development and procurement of the long range strike bomber and/or a next-generation fighter program (F-X) after 2023—a bonus that the PFE never comes close to providing.

Climbing Out of the Readiness Pit

Money gained through termination of the JSF cannot be entirely dedicated to aircraft purchase and upgrade, particularly in a case such as this in which TACAIR TAI actually increases. Some aircraft programs, such as the F-X and OA-X, are designed to "make money" by meeting current demands with an O&M cost low enough that the procurement is eventually paid for in O&M savings. Adding fuel cost increases into the sustainment calculation is difficult and not attempted,

4382 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

but this construct is more forgiving of that expense than the PFE because of lower fuel consumption.

The effectiveness of TACAIR depends upon giving particular attention to several other areas—readiness, for instance.[29] Having used readiness funds to pay for hardware bills, we must now restore the resulting decrease in readiness with funds dedicated to the TACAIR enterprise. The point of F-35 divestiture includes avoiding a permanent low-readiness state that is an extension of our current condition. The second area is magazine depth. Having temporarily given up the (presumed) capability to bring aircraft into the worst of enemy air defenses, we should not entirely relinquish the capability to hold defended targets at risk. This means additional investment in standoff weapons, including AGM-158 joint air-to-surface standoff and antiradiation missiles. It also entails an increase in improved air-to-air missile inventories and development of weapons that need not trade away performance and capabilities in order to fit into a JSF weapons bay. Finally, restoration of long-dormant anti-surface-warfare weaponry is a critical capability for the Pacific region. In the third element—systems, particularly sensors and communications—the fruits of F-35 development can be practically harvested without continuing the program itself by fielding and deploying the advanced radar, EW gear, and data links from the JSF program onto fighters and conventional bombers.

Conclusion

It is time for a rational discussion of the F-35. Such a dialogue would have to be free from the vacuum of a notional volume of contested airspace and consider the context of the complete CAF enterprise and its application across the globe. The F-35 program has long since passed the point where we can expect it to provide a substantial improvement in a broad war-fighting context over its predecessors. Designed for a European conflict that did not occur and a threat environment less advanced than the present one, the F-35 program offers little improvement over its predecessors and demands vast resources from diminishing funds.

4383 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Following the example of the Comanche program, we should consider cancelling the F-35 in favor of a robust, modernized CAF that emphasizes broad capabilities rather than occupying the short-range stealthy niche. Facing a decade of reduced budgetary authority, we must follow a prudent path towards recovery after more than 20 years of continuous combat operations. Doing so will help address a number of collateral issues, including force readiness, global reach, and the inventory of fighter/attack aircrews. Viable alternatives to the F-35 exist if we have the courage to examine them. ✪

11. Julian E. Barnes, "Warning Sounded on Cuts to Pilot Training: Air Force Responds to Cost Concerns by Reducing Flight Hours to 120 Hours or Less, Fewer Than Those of Allies—and China," *Wall Street Journal*, 19 December 2013, http://online.wsj.com/news/articles/SB10001424052702304773104579268651994849572.

12. The series of fighter force-strength reductions in the last decade has been collectively referred to as the "fighter redux" or "CAF redux." At least two major strength reductions have occurred, bringing the planned total fighter strength below 2,000.

13. The OA-X is Air Combat Command's proposal for a turboprop light attack aircraft similar to the Embraer A-29 Super Tucano or the Beechcraft AT-6B. The FT-X (sometimes the AT-X) is the proposed combat variant of Air Education and Training Command's T-38 replacement—the T-X.

14. Government Accountability Office, *F-35 Joint Strike Fighter*: *Current Outlook Is Improved, but Long-Term Affordability Is a Major Concern* (Washington, DC: Government Accountability Office, March 2013), 5, table 1, http://www.gao.gov/assets/660/652948.pdf.

15. Kari (*Irak* spelled backwards) was the French-built integrated air defense system possessed by the Iraqis prior to Desert Storm. It was only partially reconstituted after the Gulf War. The F-117A had no radar, data link, afterburner, or EW gear; in fact, it did not even use radio after crossing a hostile border.

16. Gen Mike Hostage (speech, Air Force Association, 17 September 2013), http://www.af.mil/Portals/1/documents/af%20events/17SeptAFAGen%20HostageCOMACCSpeech.pdf.

17. The global assumptions are based on current trends. Like any other set of assumptions, a radical event such as a new revolution in Iran or the fall of the regime in the DPRK is an unpredictable occurrence that would alter the list substantially. Internal US trends are perhaps easier to predict—congressional resistance to reducing the B-1 fleet is well established, the 2011 Budget Control Act is law, and fuel costs have been on a steady, upward trend for two decades (arguably four) despite increased worldwide production.

18. When the terms *high*, *medium*, and *low* are used in this context, they refer to their cost and to the intensity of the conflict for which they are optimized. "High-end" aircraft are expensive because of the advanced sensors, weapons, and communications required to conduct missions in contested airspace; "low-end" aircraft are less costly and designed for the parts of a campaign that do not demand operations in hostile airspace.

19. The F-15G is a modified F-15E+. Its EW systems are migrated from the EA-18G Growler, just as the migration of EA-6B systems to the F-111 Aardvark created the EF-111A Raven.

20. The MQ-9, funded from the intelligence, surveillance, and reconnaissance (ISR) portfolio, is left alone since it does not compete for funds directly with other TACAIR.

21. We did not utilize any funding from the ISR portfolio, which covers the MQ-9, or the global strike portfolio, which covers the B-52 and B-2.

22. The tradespace analysis tool includes not only purchase costs but also sustainment costs.

23. The two-seat fighter squadron is more expensive than its single-seat counterpart for obvious reasons. However, in an environment where we have insufficient cockpits to go around, the two-seat fighter squadrons double the number of absorbable cockpits without a concurrent doubling of costs.

24. Estimated O&M costs for the F-35 currently hover around $32,000 per flying hour compared to the F-16's $19,000; the A-10's $18,000; and the F-15E's $28,000 (Air Force Total

4385 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Ownership Cost database, FY 2013). By comparison, the Air National Guard's AT-6B test program operated for two years with an hourly flying cost of less than $1,500.

25. For detailed discussions of the potential impact of a light attack aircraft on Air Force operations in Operation Iraqi Freedom and Operation Enduring Freedom, see Michael Pietrucha and J. David Torres-Laboy, "Making the Case for OA-X," *Air Land Sea Bulletin* 2010-1 (January 2010): 15–18; and Michael Pietrucha, "Logistical Fratricide," *Armed Forces Journal* 149, no. 6 (January/February 2012): 14–37.

26. Although the term *guerrilla warfare* derives from the Peninsular War in Spain against the Emperor Napoleon, historical examples of irregular warfare are legion. The Romans, for example, fought far more irregular conflicts than classical major combat operations such as the Punic Wars and had an adaptable military structure that varied by time and place, depending greatly on the nature of their adversaries.

27. A fifth-generation penetrating force is not necessary to produce coercive effects against a large, maritime-dependent nation. Approaches used against Japan in early and mid-World War II are but one example of an effective strategy that can be conducted with airpower and operated at a distance without the need for mass penetration of air defenses.

28. Absorbable cockpits—operational flying positions filled by fighter/attack aircrews—are a measure of the ability to develop and season aircrews.

29. Given this article's focus on TACAIR and the necessity of neglecting the bombers, it must be noted that readiness, system upgrades, and magazine depth are bomber issues as well.

Col Michael W. Pietrucha, USAF

Colonel Pietrucha (BA, Pennsylvania State University; MA, American Military University) is the individual mobilization augmentee to the Pacific Air Forces (PACAF) A5/8, Headquarters PACAF, Hickam Field, Hawaii. Commissioned through the AFROTC program in 1988, he has served at Spangdahlem AB, Germany; Nellis AFB, Nevada (twice); RAF Lakenheath, United Kingdom; Langley AFB, Virginia; and the Pentagon. As an instructor electronic warfare officer in the F-4G Wild Weasel and, later, the F-15E, he has amassed 156 combat missions over 10 combat deployments. An irregular warfare operations officer, Colonel Pietrucha has two additional combat deployments in the company of US Army infantry, combat engineer, and military police units in Iraq and Afghanistan.

Religion in Military Society

Reconciling Establishment and Free Exercise

Chaplain, Maj Robert A. Sugg, USAF

The First Amendment of the US Constitution's Bill of Rights declares that "Congress shall make no law respecting an establishment of religion, or prohibiting the free exercise thereof." In military society, a unique collision of "rights" between nonestablishment and religious freedom requires an equally unique accommodation of religious practices—that is, *an agreement that allows people, groups, and so forth, to work together*. Many recent news reports indicate that our commanders and senior leadership lack clear guidance for

4387 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

parsing the complicated ground that separates "church and state." Because both the (non) Establishment and Free Exercise Clauses of our Constitution have equal weight, the government may not become "entangled" in religion or show it hostility.[1] By examining military society through both lenses—(non) establishment and free exercise—commanders can more clearly understand their responsibilities to service members as they carry out the mission. This article addresses establishment and free exercise in light of constitutional case law, offering four simple tools for making better decisions.

The Military Community

Military installations are isolated communities of culturally diverse people whose right of freedom of religion has been limited for the sake of the mission. Service members are American citizens protected by the Constitution and are on loan from 50 sovereign states while they continue to advocate for their legal and social preferences through the voting booth. In civilian communities, social and cultural standards found in laws and policies differ from town to town and state to state; they are established from the bottom up. For example, a Christian community will tend toward Christian standards; a Jewish community, Jewish standards; a progressive community, progressive standards; or a family community, family standards. In local politics, the religious and the secular all have equal access to the voting booth. In contrast, on military installations, all religious institutions have been fenced out, and political interaction between religious communities and elected officials does not exist. On fenced military communities, commanders are expected to maintain the constitutional balance of (non) establishment and free exercise. To do so, they have both a judge advocate general (JAG) and a chaplain to advise them.

To make things more difficult, military installations are a public-private hybrid consisting of government mission and family life. For instance, an aircraft hangar may be used for maintenance in the morning and a school-sponsored event in the afternoon. Funding options

4388 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

are equally confusing. Taxpayer dollars are limited to direct mission requirements that include mandatory funding for chaplain salaries, chapel buildings, and religious worship services while chapel tithes and offerings from the collection plate are also used to fund unit-focused programs such as barbecues in the dormitories and work centers. Commanders must understand that simply scrubbing the religious from military installations or restricting it to the interfaith chapel is not what the writers of our Constitution intended. Consequently, the provision of the right of free exercise through religious accommodation is a direct mission requirement.[2] From the assembly of the Continental Army onward, citizen Soldiers, Sailors, Airmen, and Marines are primarily religious people with religious families, holding religious ethics and living religious lives on government property.

Establishment and Free Exercise: A Condition of Respect

The US Constitution ensures that religion in the public square does not end on military installations. Some people believe that neutrality toward church and state equates to the absence of the religious on government property and in government operations. By using constitutional case law, we will see that this position is emphatically false. The court of *Lemon v. Kurtzman* observes that "judicial caveats against (government entanglement in religion) must recognize that the line of separation, far from being a 'wall,' is a blurred, indistinct, and variable barrier depending on all the circumstances of a particular relationship."[3] Additionally, *Lynch v. Donnelly* notes that

> no significant segment of our society, and no institution within it, can exist in a vacuum or in total or absolute isolation from all the other parts, much less from government. "It has never been thought either possible or desirable to enforce a regime of total separation." . . . Nor does the Constitution require complete separation of church and state; it affirmatively mandates accommodation, not merely tolerance, of all religions, and forbids hostility toward any. . . . Anything less would require the "callous indifference" we have said was never intended by the Establishment Clause. . . . Indeed, we have observed, such hostility would bring us into "war

4389 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

> with our national tradition as embodied in the First Amendment's guaranty of the free exercise of religion."[4]

Thomas Jefferson used the term *wall of separation*, writing to religious people in 1802 for the express purpose of allaying the churches' fears that the government would attempt to control their religion. Jefferson stated, "Believing with you that religion is a matter which lies solely between Man & his God . . . I contemplate with sovereign reverence that act of the whole American people which declared that their legislature should 'make no law respecting an establishment of religion, or prohibiting the free exercise thereof,' thus building a wall of separation between Church & State."[5] Jefferson intended the exact opposite of humanists' use of the phrase today in their attempt to keep religion out of government. In fact,

> in 1962, [Supreme Court] Justice Potter Stewart complained that jurisprudence was not "aided by the uncritical invocation of metaphors like the 'wall of separation,' a phrase nowhere to be found in the Constitution." Addressing the issue in 1985, Chief Justice William H. Rehnquist lamented that "unfortunately the Establishment Clause has been expressly freighted with Jefferson's misleading metaphor for nearly 40 years."[6]

Far from banning religion in the public square, the (non) Establishment and Free Exercise Clauses were drafted in a way that allowed people of all faiths—and none—to equally live out their lives on common ground. The founding fathers intended to require American citizens to maintain a condition of mutual respect while they shared the same space. A much better metaphor than "separation of church and state" is "a level playing field for all political issues to be heard equally."[7] Americans cannot choose one of two paths to arrive at common ground. The nonreligious cannot walk the road of (non) establishment and arrive at free exercise. In the same way, the religious cannot walk the road of free exercise and arrive at (non) establishment. Common ground is a level playing field upon which both parties must agree to live as coequals. Respectfully sharing space on a level playing field involves four constitutional principles.

4390 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Hostility toward Religion Is Not Neutrality

On military installations, some of what passes as neutrality toward religion is actually hostility—the primary concern of the religious majority on military installations today. We have already examined the Supreme Court statement that the Constitution "affirmatively mandates accommodation, not merely tolerance, of all religions, and forbids hostility toward any." Additionally the court of *Rubin v. City of Lancaster* cautions that "the danger that such efforts to secure religious 'neutrality' may produce 'a brooding and pervasive devotion to the secular and a passive, or even active, hostility to the religious.'"[8] A recent survey of Air Force chaplains included the statement "I believe Airmen are free to practice their religion except where military necessity dictates otherwise."[9] The chaplains were asked to agree or disagree on a scale of one to four. A subsequent memorandum from the chief of chaplains notes that 82 percent of chaplains believe that Airmen can practice their religion freely.[10] The corollary holds that, of approximately 500 active duty chaplains, 90 believe that Airmen cannot practice their religion freely. An additional concern is that the survey did not measure the ethos—the atmosphere of free exercise. In other words, is there a pervasive institutional bias against the religious that causes religious people or military leadership to "walk on eggshells"? To walk on eggshells in the matter of religion is not evidence of neutrality but of hostility.

God Is Presupposed on Government Property

Lynch v. Donnelly affirms that "there is an unbroken history of official acknowledgment by all three branches of government of the role of religion in American life from at least 1789" and that "we are a religious people whose institutions presuppose a Supreme Being."[11] The courts imply that because our government as a whole presupposes a supreme being, each department of our government must also presuppose a supreme being. The Department of Defense (DOD) is not free to banish God from the public square. In principle, the writers of the

4391 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Constitution clearly expressed that God is not confined to the chapel but walks the parade ground, the maintenance bay, and the flight line.

For example, with regard to paintings, sculpture, and other displays, *Lynch v. Donnelly* affirms the propriety of nonproselytizing religious art in public places:

> Art galleries supported by public revenues display religious paintings of the 15th and 16th centuries, predominantly inspired by one religious faith. The National Gallery in Washington, maintained with Government support, for example, has long exhibited masterpieces with religious messages, notably the Last Supper, and paintings depicting the Birth of Christ, the Crucifixion, and the Resurrection, among many others with explicit Christian themes and messages. The very chamber in which oral arguments on this case were heard is decorated with a notable and permanent—not seasonal—symbol of religion.[12]

The walls of many DOD headquarters buildings, dining facilities, and other common areas are adorned with art and sculpture of many kinds. Art and sculpture with religious overtones are not, on their face, subject to removal or limitation. Regarding symbols of religion, *Lynch v. Donnelly* affirms the constitutionality of the National Day of Prayer, paid federal holidays of religious origin, the phrase "one nation under God" in our pledge of allegiance, the phrase "in God we trust" on our currency, and Christmas crèches owned and displayed by the government for secular purposes.[13] Religion is welcomed to pervade the public square, and it is the commander's constitutional duty to ensure that religion is welcome on military installations.[14]

God May Be Invoked and Welcomed during Government Business

Whether from a military chaplain or a volunteer from a local house of worship, prayer at government events is constitutional.[15] *Marsh v. Chambers* affirms the propriety of prayers during government assemblies.[16] These prayers are, and have always been, religious in nature and not simply ceremonial.

4392 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Regarding religious practitioners with whom he disagreed, founding father Samuel Adams said that "he was no bigot, and could hear a prayer from a gentleman of piety and virtue, who was at the same time a friend to his country."[17] According to *Lynch v. Donnelly*, "It is clear that neither the 17 draftsmen of the Constitution who were Members of the First Congress, nor the Congress of 1789, saw any establishment problem in the employment of congressional Chaplains to offer daily prayers in the Congress, a practice that has continued for nearly two centuries. It would be difficult to identify a more striking example of the accommodation of religious belief intended by the Framers."[18] Religious invocations at government events are an acknowledgement that people of faith have an allegiance to "the Supreme Judge of the world," who is higher than any law of humankind.[19] If we use the level playing field analogy, then providing a respectful presence for a religious prayer is no different than doing so for another nation's national anthem.[20] One does not have to agree with all members of a diverse population to be respectful.

The Threat of Litigation Cannot Be Grounds for Marginalizing the Religious

Lynch v. Donnelly affirms that "a litigant cannot, by the very act of commencing a lawsuit, however, create the appearance of divisiveness and then exploit it as evidence of entanglement."[21] Ethical leaders must be concerned about good order and discipline.[22] However, the principle of good order and discipline cannot be used as a carte blanche to bulldoze all traces of the constitutional rights of a vulnerable class of citizens. Balance is critical! On the one hand, we must not violate the Establishment Clause by offending the nonreligious with the appearance of a government-endorsed religion. On the other hand, we must not violate the Free Exercise Clause by demonstrating hostility to religion through the systematic purging of everything with a religious overtone. Angry agitators, religious or atheist, must not be the determining factor for leadership decisions. The courts have provided much guidance for walking this tightrope and have supplied the

4393 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

groundwork for ethical decision making in a military context. In partnership, the JAG and Chaplain Corps must revisit the US Constitution and case law to move forward *collaboratively*, crafting policies and using explicit language that describes a level playing field on which respectful people may agree to disagree. In all cases, DOD policies must clearly define and prohibit hostility toward religion.

Four Tools for Parsing Establishment and Free Exercise

In the past few years, installation commanders in a number of reported incidents have apparently been advised to focus exclusively on the Establishment Clause in an attempt to secure religious neutrality. Unfortunately, in some cases their intended defensive action for (non) establishment was rightfully perceived as offensive to free exercise. In the same way we use 3-D movie glasses, commanders must intentionally look through both lenses of (non) establishment and free exercise to see the constitutional picture clearly. The following four simple tools for discerning the line between the Establishment and Free Exercise Clauses use court decisions as a guide. These court decisions are few, readily available, and easily read.

Historic Practice

Marsh v. Chambers tells us that the constitutionality of government-paid chaplaincy and legislative-type prayer is not found in any "test" but in historic practice.[23] Responding to a suit in which a complainant objected to a government-paid chaplain for the Nebraska Legislature, the Supreme Court held that

> the Nebraska Legislature's chaplaincy practice does not violate the Establishment Clause. . . . The practice of opening sessions of Congress with prayer has continued without interruption for almost 200 years, ever since the First Congress drafted the First Amendment, and a similar practice has been followed for more than a century in Nebraska and many other states. . . . Standing alone, historical patterns, cannot justify contemporary violations of constitutional guarantees, but there is far more here

4394 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

> than simply historical patterns. In this context, historical evidence sheds light not only on what the draftsmen intended the Establishment Clause to mean, but also on how they thought that Clause applied to the practice authorized by the First Congress—their actions reveal their intent.[24]

The court of *Marsh v. Chambers* appeals to the contemporary practices of those who actually penned the law. The writers of the Constitution did not forbid what they themselves permitted.[25] When confronted with questions about the scope and practice of chaplains and public prayer, one should employ the first tool to determine if historic practice exists.

Context

Lynch v. Donnelly upheld the constitutionality of a private association to erect a Christmas display on public property on the basis of context:

> The Court has recognized that "total separation is not possible in an absolute sense. Some relationship between government and religious organizations is inevitable." . . . The narrow question is whether there is a secular purpose for Pawtucket's display of the creche. . . . Here, whatever benefit there is to one faith or religion or to all religions, is indirect, remote, and incidental; display of the creche is no more an advancement or endorsement of religion than the Congressional and Executive recognition of the origins of the Holiday itself as "Christ's Mass," or the exhibition of literally hundreds of religious paintings in governmentally supported museums.[26]

Another case, *County of Allegheny v. American Civil Liberties Union*, concerns the constitutionality of a crèche placed on the "Grand Staircase" of a county courthouse. The crèche was part of a larger holiday display dispersed throughout the grounds. The court found that the *location* of the crèche was unconstitutional, based on the context:

> The creche sits on the Grand Staircase, the "main" and "most beautiful part" of the building that is the seat of county government. . . . No viewer could reasonably think that it occupies this location without the support and approval of the government. Thus, by permitting the "display of the creche in this particular physical setting," . . . the county sends an unmistakable message that it supports and promotes the Christian praise to God that is the creche's religious message.[27]

4395 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

This case tells us that discerning the line between "a secular purpose" and promoting a religion involves not the religious presence or practice but the context in which it is found. A frontline supervisor, for example, may be religious and live his or her religious life at work. A supervisor, however, must not live this religious life in such a way that it would give *reasonable* people the appearance of favoring the religious over the nonreligious or others of differing faiths. It is a difficult line, but simply "playing it safe" and sanitizing the area violates the supervisor's constitutional rights. When confronted with an object or practice with religious overtones, one should use the second tool to observe the context.

The Lemon Test

> *In the absence of precisely stated constitutional prohibitions, we must draw lines with reference to the three main evils against which the Establishment Clause was intended to afford protection: "sponsorship, financial support, and active involvement of the sovereign in religious activity."*
>
> *—Lemon v. Kurtzman*

This three-point litmus test, also known as the "*Lemon* test," determines the dividing line between free exercise and establishment.[28] A more recent case, *Lynch v. Donnelly* (1984), offers additional clarification for application: "In the line-drawing process, we have often found it useful to inquire whether the challenged law or conduct has a secular purpose, whether its principal or primary effect is to advance or inhibit religion, and whether it creates an excessive entanglement of government with religion."[29] The descriptions and examples below are brief. Commanders and senior leadership would benefit greatly by reading the court decision for themselves.

The first point of the *Lemon* test evaluates for the legitimacy of a secular purpose. The question at hand is, Does the mere presence of a religious symbol or practice on government property imply government *sponsorship* for a specific religion or religion over nonreligion?

4396 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The *Lynch v. Donnelly* court addresses the often misused metaphor of a "wall" of separation between church and state, observing that the "metaphor itself is not a wholly accurate description of the practical aspects of the relationship that in fact exists between church and state" and that "total separation is not possible in an absolute sense."[30] Religious symbols and celebrations may be found on government property for secular reasons and are not, in themselves, evidence of government sponsorship.

The second point of the *Lemon* test evaluates whether or not a symbol or practice's primary effect advances or inhibits religion. This is assessed through context. Regarding the City of Pawtucket's practice of including a crèche in its larger holiday display, the court found that, as mentioned above, "whatever benefit there is to one faith or religion or to all religions, is indirect, remote, and incidental; display of the crèche is no more an advancement or endorsement of religion than the Congressional and Executive recognition of the origins of the Holiday itself as 'Christ's Mass,' or the exhibition of literally hundreds of religious paintings in governmentally supported museums." Again the issue is context. Whether we are looking at a holiday scene or viewing a picture on a wall, the government's question should be, In the eyes of a reasonable person, does this act or display give the appearance of government advancement or inhibition of a particular religion or religion over nonreligion?

The third point of the *Lemon* test evaluates unnecessary government entanglement. In other words, if we go down this road, will the government have to spend significant resources in policing and monitoring to ensure that secular-religious lines are not crossed or that no significant amount of manpower and funding is expended? The court found that

> entanglement is a question of kind and degree. . . . There is no evidence of contact with church authorities concerning the content or design of the exhibit prior to or since Pawtucket's purchase of the creche. No expenditures for maintenance of the creche have been necessary; and since the city owns the creche, now valued at $200, the tangible material it contrib-

4397 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

> utes is *de minimis*. In many respects, the display requires far less ongoing, day-to-day interaction between church and state than religious paintings in public galleries.[31]

Allowing the religious time and space in the public square is not government entanglement with religion. Even the government purchase and maintenance of religious items for secular purposes do not constitute entanglement with religion.

Let us examine three recent examples of DOD intervention in religious issues and apply the *Lemon* test to each one. Again, the three questions are as follows: (1) Does the mere existence of a religious symbol or practice on government property imply government sponsorship for a specific religion or religion over nonreligion? (2) Does the context of a religious symbol or practice on government property advance or inhibit a specific religion or religion over nonreligion? (3) Will the religious symbol or practice be an entanglement to the government due to significant amounts of monitoring, funding, or manpower?

The first example comes from a June 2013 news story reporting that "an Air Force video saluting first sergeants—produced by an Air Force Chaplain—was removed by order of the Pentagon because it mentions the word 'God,' even though it was never intended as required viewing."[32] The video was produced in conjunction with a number of first sergeants and intended as a humorous parody of a Super Bowl commercial. In directing the removal of the video, "the Chief of the Air Force News Service Division stated incorrectly, . . . 'Proliferation of religion is not allowed in the Air Force or military. How would an Agnostic, Atheist or Muslim serving in the military take this video?'"[33] Applying the *Lemon* test, we ask, Does the video have a secular purpose? Yes. Is the video's primary effect to advance or inhibit religion? No. Does the video foster excessive government entanglement? No. If all the facts are as stated, then the Pentagon's actions appear to violate the Constitution's First Amendment by favoring nonreligion over religion and evidence of hostility toward religion. Additionally, the Penta-

4398 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

gon's position was eventually reversed. No evidence of malice exists—only the lack of clear, objective written guidance from our most senior policy makers.

The second example is from a news report that the Air Force's Rapid Capabilities Office (RCO) removed the Latin name *Dei* (God) from its logo after objections by the Military Association of Atheists and Freethinkers: the "RCO patch logo previously included the motto 'Opus Dei Cum Pecunia Alienum Efficemus' (Doing God's Work with Other People's Money), an inside joke among RCO members. Caucus members say it was changed to 'Miraculi Cum Pecunia Alienum Efficemus' (Doing Miracles with Other People's Money)."[34] Applying the *Lemon* test, we ask, Does the logo have a secular purpose? Yes. Is the logo's primary effect to advance or inhibit religion? No. Does the logo foster excessive government entanglement? No. If all the facts are as stated, then the Pentagon's actions appear to violate the Constitution's First Amendment by favoring nonreligion over religion and evidence of hostility toward religion. Additionally, atheist groups have petitioned our courts for years to remove the phrase "in God we trust" from our monetary notes and coins.[35] The courts have repeatedly and emphatically rejected their argument: "In dismissing the suit, U.S. District Judge Harold Baer, Jr., wrote that 'the Supreme Court has repeatedly assumed the motto's secular purpose and effect' and that federal appeals courts 'have found no constitutional violation in the motto's inclusion on currency.' He added that while the plaintiffs might feel offended, they suffered no 'substantial burden.'"[36]

The third example involves the removal of religious artwork from a dining facility. A painting entitled *Blessed Are the Peacemakers*, a 9-11 memorial gift to the installation, had long been displayed on a dining facility's wall. An atheist organization petitioned for and was granted the removal. A news report also relates that the wing commander said that "he will be ordering another inspection to rid his base of anything else like what had been hanging in the dining hall."[37] Applying the *Lemon* test, we ask, Does the artwork have a secular purpose? Yes. Is

4399 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

the artwork's primary effect to advance or inhibit religion? No. Does the artwork foster excessive government entanglement? No. If all the facts are as stated, then the commander's actions appear to violate the Constitution's First Amendment by favoring nonreligion over religion and evidence of hostility toward religion. Another report indicated that the commander maintained that "the painting violated military regulations governing the free exercise of religion" and that "the . . . [regulation] states that we will remain officially neutral regarding religious beliefs—neither officially endorsing nor disapproving any faith belief or absence of belief."[38] The commander cited the regulation correctly, but his interpretation was faulty. He had no "test" available to determine the ground between neutrality and hostility.

The three-part *Lemon* test is a simple tool for items with religious content. Each point of this test involves some subjectivity. Thus, it is critical that *both* the JAG, arguably representing (non) establishment, and the chaplain, representing free exercise, have equal input into a commander's decision process. We must use the 3-D glasses! When faced with an object or practice with religious overtones, ethical leaders should utilize a respectful, methodical, and equitable process to find the balanced position. The third tool in the box is the *Lemon* test.

Bottom-Up Consensus

Commanders at all levels are unelected stewards who have limited legal authority to constrain constitutional rights to accomplish their missions. Primary drivers for poor command decisions include haste, misinformation, or personal bias. Regarding removal of the artwork from the dining facility, for instance, a report noted that the non-DOD complainant "gave the Air Force an hour to take action" and that the subsequent removal took place in 56 minutes.[39] This was a top-down decision. When dealing with social issues, religious or otherwise, the community must be consulted from the bottom up and must take time to contact the JAG, chaplain, senior leadership, and the installation's private organizations. The Air Force's integrated delivery system

4400 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

should have an opportunity to broker a peaceful settlement among organizations. Any *appearance* of the imposition of a commander's personal preference for cultural and religious standards that exceed those necessary for the mission may be construed as social engineering and must be seen as a catastrophic moral violation of professional ethics. Commanders must never use their positions to impose any religious or cultural standard, whether Christian, Jewish, Muslim, Wiccan, atheist, conservative, or progressive. In social issues within a closed community, "good order and discipline" is not a top-down affair.[40] Ethical commanders allow members of their community to speak to one another, advocate for their positions, and, most of all, be respected. Then and only then do ethical commanders make command decisions. The fourth tool is bottom-up consensus.

Legal "Tests" or Historic Practice?

In 2007 the *Air Force Law Review* published an article entitled "Religion in the Military: Navigating the Channel between the Religion Clauses."[41] For seven years, it has remained a significant "think piece" for making Air Force policy; indeed, the article is listed as a reference in the current Air Force JAG publication *The Military Commander and the Law*.[42] The legal assessments and conclusions of the authors—Maj David E. Fitzkee, USA, retired, and Capt Linell A. Letendre, USAF—regarding the Chaplain Corps's scope and practice and the provision of public prayer are horribly wrong.

Referring to *Marsh v. Chambers* (1983), Fitzkee and Letendre correctly remark that "the court has upheld an opening prayer for a legislative session relying on the historical exception but has denied a moment of silence in public schools using the *Lemon* analysis."[43] The authors clearly delineate between historically sanctioned prayers at a historically rooted, adult-dominant event from prayers at a child-dominant public school event. Then, inexplicably, they choose to argue the validity of historical prayer in military settings (*Marsh* language) from the same category as prayer at school graduations and

4401 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

football games (*Lemon* language).[44] In short, they switch from historical precedent to "tests." Fitzkee and Letendre complete their conversion with the following statement: "When facing the challenging question of prayer at an official military function, one must navigate through the array of legal opinions deliberately and with full understanding of the particular context in which the prayer will be given."[45] Absolutely not! In a legislative or military setting, prayer is found constitutional through historic practice; context is irrelevant. Worse, they end their analysis by declaring,

> Unlike a school environment, where students can vote on whether or not to have a message and decide what the content of the message should be, the military does not put to a vote whether to have an "opening message" at a change-of-command or a dining-in. Instead, a commander typically decides that there will be an invocation and routinely asks a chaplain to perform this duty. This overt government involvement, both in the decision making and delivery of an invocation, results in clear government speech, thereby compelling Establishment Clause analysis.[46]

Do Fitzkee and Letendre really believe that the framers of our Constitution held that military commanders who request chaplain invocations at change-of-command ceremonies are guilty of violating the Establishment Clause? The Supreme Court does not agree.[47] To examine the constitutionality of the Chaplain Corps's scope and practice, one must consult the best court ruling—*Marsh v. Chambers* (historic practice).

A Word about Ceremonial Deism

At the time of this writing, in *Town of Greece v. Galloway*, the Supreme Court is deliberating the consequences of a relatively new artificial construct called "ceremonial deism."[48] At issue is "whether the court of appeals erred in holding that a legislative prayer practice violates the Establishment Clause."[49] In other words, is a prayer at a government event really a prayer? To understand the debate, one must grasp the origins of ceremonial deism. The original term comes from an unpublished 1962 lecture at Brown University given by Yale Law

4402 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

School dean Eugene Rostow in which he proposed that "certain types of religious speech, which he called 'ceremonial deism,' were 'so conventional and uncontroversial as to be constitutional.'"[50] Reflecting on this reference in 1984, Justice William Brennan offered his dissenting opinion in *Lynch v. Donnelly*:

> While I remain uncertain about these questions, I would suggest that such practices as the designation of "In God We Trust" as our national motto, or the references to God contained in the Pledge of Allegiance to the flag can best be understood, in Dean Rostow's apt phrase, as a form of "ceremonial deism," protected from Establishment Clause scrutiny chiefly because they have lost through rote repetition any significant religious content.[51]

In his ponderings of uncertainty, Justice Brennan implies that he personally finds that these religious references have no "significant religious content." The original intent of the authors is lost on him.

In 1989 Justice Brennan's thoughts became a legal player through the majority opinion of *County of Allegheny v. American Civil Liberties Union*:

> The concurrence, in contrast, harmonized the result in *Marsh* with the endorsement principle in a rigorous way, explaining that legislative prayer (like the invocation that commences each session of this Court) is a form of acknowledgment of religion that "serve[s], in the only wa[y] reasonably possible in our culture, the legitimate secular purposes of solemnizing public occasions, expressing confidence in the future, and encouraging the recognition of what is worthy of appreciation in society." . . . The function and history of this form of ceremonial deism suggest that "those practices are not understood as conveying government approval of particular religious beliefs."[52]

With regard to legislative prayer, the justices chose not to refute *Marsh*'s historic-practice argument and so added a new proposition on top of it. The *County of Allegheny* court stated that it has "harmonized" *Marsh* with "this form of ceremonial deism" so that legislative prayer should be viewed as a method of "solemnizing public occasions, expressing confidence in the future, and encouraging the recognition of what is worthy of appreciation in society" (see above). But by artifi-

4403 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

cially separating the act of prayer from its religious content, the Supreme Court has created additional confusion. The decision of *Town of Greece v. Galloway* may be intended as clarification. Will the Supreme Court uphold the original intent of the framers of the Constitution, meaning that public prayer is an example of free exercise, or will it overturn *Marsh* and pursue ceremonial deism in the name of (non) establishment? It is doubtful that the Supreme Court would overturn *Marsh*. However, it is almost certain that it will also continue to "harmonize" the founders' religious intent with antireligious ceremonial deism.

In the foreseeable future, regardless of *Town of Greece v. Galloway*, the American people should expect that the painting *The Baptism of Pocahontas* will remain on the Capitol Rotunda wall and that the National Gallery of Art will continue to display *Rabbi* and fund the maintenance of the *The Sacrament of the Last Supper*.[53] The Senate chaplain will continue his or her duties, ensuring that "all sessions of the Senate have been opened with prayer, strongly affirming the Senate's faith in God as Sovereign Lord of our Nation."[54] Each of these long-standing government practices provides examples of how our commanders should manage religion on their installations.

Conclusion

In the twenty-first century, US military society has entered a new era of cultural change, and we have been given few tools to make the transition. Indeed, we have not even framed the questions. Military leaders have sworn to support and defend the Constitution of the United States, and service members depend upon those in authority to act honorably. Leaders must be concerned about good order and discipline but must never use this as an easy excuse to sanitize religion. We can neither endorse religion nor show it hostility. We should use the four tools for discerning the line between establishment and free exercise. The only way to determine constitutionality in matters of religion is to look through both the 3-D lenses of (non) establishment and free

4404 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

exercise. In practice, the JAG office represents the commander and has given the appearance of advocating for the institution over the rights of the individual. The scale has tipped in favor of (non) establishment. The scale must now be balanced to include the weight of free exercise. It is most critical that the Chaplain Corps "get smart" on constitutional law. Our JAGs and Chaplain Corps should transparently work together to restore First Amendment balance throughout the DOD. Constitutional free exercise must always remain a positive principle to be celebrated and not simply the dark side of (non) establishment. ✪

Chaplain, Maj Robert A. Sugg, USAF

Chaplain Sugg (MDiv, Seminary of the East; BS, Charter Oak State College; MS, Tarleton State University) is the staff chaplain for the USAF Expeditionary Center, Joint Base McGuire-Dix-Lakehurst, New Jersey. As course director and academic instructor, he developed and delivered cutting-edge education and training for Chaplain Corps personnel deploying to high-risk environments. As staff chaplain, he provides pastoral care and counseling to a staff of 400 and a student population of 24,000 while advising Expeditionary Center leaders on matters of religious accommodation, ethics, and morale. Chaplain Sugg assists the joint base's Chaplain Corps to ensure free exercise of religion and to provide pastoral care, counseling, worship, rites, and sacraments to joint base personnel and their families. He is a credentialed pastoral counselor with over 4,000 hours of client counseling, 870 hours of clinical supervision, and 8 units of Clinical Pastoral Counseling. Chaplain Sugg has been the senior pastor for 12 congregations, including military communities in South Korea, Kuwait, and Saudi Arabia.

4407 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Cataclysm: General Hap Arnold and the Defeat of Japan by Herman S. Wolk. University of North Texas Press (http://untpress.unt.edu/), 1155 Union Circle no. 311336, Denton, Texas 76203-5017, 2012, 352 pages, $24.95 (hardcover), ISBN 1-574412-81-7; $19.95 (softcover), ISBN 1-574414-73-9.

In *Cataclysm* Herman S. Wolk argues that Gen Hap Arnold counted upon the B-29 campaign as a means to an end (i.e., the continued future of the Army Air Forces [AAF] and the effort to make it an independent service). The author does not indicate that Arnold himself ever openly promoted strategic bombing as the decisive tool for victory and, thus, a proof of concept. However, he does convincingly present the case—through Arnold's actions—that privately he thought that the strategy of air bombardment and the AAF's participation in creating a sea blockade could bring about the war's end without a costly ground invasion of the Japanese home islands.

The book includes an introduction and seven chapters, the introduction and last chapter acting as bookends. In the introduction, Wolk identifies his goal of uniquely examining the interconnected roles that General Arnold played in the development and deployment of the B-29 and the establishment of Twentieth Air Force as well as the strategies and policies of an air campaign whose design could have ultimately led to the defeat of Japan. He also notes that his study draws on a source little used in the examination of that defeat—the wartime accounts of the Japanese themselves, a source that gives particular credence to his thesis. In the final chapter, "Who Was Hap Arnold?," Wolk addresses the impact of Arnold's determination to bring about an independent Air Force, including his futurist vision of a radically different aviation technology. The central chapters cover the general's career from his early days in aviation to the period immediately following the Second World War. Each chapter develops the unfolding story of policy, strategy, and command that emerged from the debate about whether an air cam-

4408 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

paign and naval blockade could bring about a Japanese surrender or whether a ground invasion was necessary. Of course, the successful use of the atomic bombs rendered that debate moot.

Within the central chapters, Wolk details Arnold's relationship with President Franklin Roosevelt and his cabinet members, such as Harry Hopkins; his struggle to ready the B-29 for operational deployment in spite of numerous technological problems; and his successful establishment of Twentieth Air Force as an independent command under his direct leadership. The general's willingness to replace the Twentieth's operational commanders when he felt they were not producing the desired results demonstrates his emphasis on the success of the Pacific air campaign. In Gen Curtis LeMay, Arnold found a commander who would lead the XI Bomber Command and produce those results. LeMay's shift from high-altitude precision bombing to low-altitude area incendiary bombing brought about the destruction of Japan's dispersed urban industries and, Wolk maintains, the collapse of its will to continue prosecuting the war. Though not *the* factor that brought about surrender, Wolk convincingly argues that strategic bombing and the AAF's involvement in the sea mine campaign were key elements in setting the stage for Japan's capitulation when confronted with the destructiveness of the atomic bombs.

I found this book repetitive at times, particularly in its first half, but I also found it an enlightening and enjoyable read. As the author observes in the introduction, this study is not an operational history but an examination of policy, strategy, and command. As such, Wolk's narrative of Arnold impressed me. The general's impact on the air campaign in the Pacific theater and the interconnected drive to maintain operational independence for Twentieth Air Force laid the foundation for the creation of an independent postwar Air Force. *Cataclysm* is a welcome addition to literature on the air campaign in the Pacific, the debate over the effectiveness of a strategic air campaign, and Arnold's vision of how—through the contributions of a wartime campaign—the AAF could transform itself into a coequal service.

War over the Trenches: Air Power and the Western Front Campaigns, 1916–1918 by E. R. Hooton. Ian Allan Publishing (http://www.ianallanpublishing.com), 12 Ethel Street, Birmingham B2 4BG, UK, 2010, 352 pages, $18.79 (hardcover), ISBN 9780711034150.

The impetus for the rise of American airpower does not begin with Billy Mitchell in the interwar years but within the Anglo-German competition for aerial dominance during World War I. That is just one of the themes that emerges from E. R. Hooton's superbly researched volume *War over the Trenches: Air Power and the Western Front Campaigns, 1916–1918*. The author provides the reader with what may be the first detailed study of the contributions of airpower during the war.

Most airpower studies tend to gloss over World War I, focusing on airpower theory and its development afterward but rarely addressing the actual use of airpower in that conflict. One sees the same tendency in the Air Force's professional military education for officers, resulting in a fairly superficial view of airpower's contributions. Hooton seeks to fill this gap in historical research by giving the reader comprehensive descriptions (both quantitative and qualitative) of the employment of airpower on the Western Front from 1916 to 1918.

The author chronicles the evolution of airpower at this time by dividing the book into separate periods by chapter. In each, analysis first addresses the campaign from the perspective of the ground commander before discussing the contributions of airpower. Intertwined with the historical accounts is considerable detail about tactical- and operational-level air operations, which Hooton uses to explore the beginnings of many of today's airpower roles.

For example, he examines the Allied successful campaign in the Somme from June to November 1916, describing the static form of warfare that killed hundreds of thousands of troops in the process of taking small stretches of ground (p. 91). Airpower relieved much of the

4410 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

stalemate. During this battle, British airmen under Marshal of the Royal Air Force Hugh Trenchard flew more than 21,400 combat sorties (p. 124). Regarding the Somme, Hooton documents one of the first realizations of the split between tactical- and operational-level air operations: "Trenchard believed this outer air battle both on the main battle front and on its periphery was the key to success in the Tactical Level inner air battle to keep the enemy air force at arm's length" (p. 97). Additionally, he notes the emphasis on strategic bombing (a concept applied emphatically in World War II): "Sustained bombing was the other plank of Trenchard's strategy, the aim being to inflict material damage, to divert enemy resources and to dilute enemy air power on the main battlefront" (p. 113). Between 1916 and 1918, aircraft dropped 25,000–30,000 tons of bombs on the Western Front (p. 77). Compared to the tonnage dropped during the next war, these totals may seem insignificant, but in the context of World War I, they are noteworthy, given the fact that bombing began early in the war with pilots releasing hand-grenade-size explosives directly from the cockpit.

In *War over the Trenches,* the author offers the reader unparalleled information about air operations on the Western Front in World War I. That said, the reader should buckle in and brace for 65 detailed tables and an impressive list of sources in multiple languages. Clearly, Hooton addresses a fundamental gap in airpower history, having produced a body of knowledge that should be an asset to both the researcher and recreational reader. For today's airmen, this book makes for a very interesting read—indeed, a must-read for any instructor who needs the context to talk intelligently about the contributions of airpower during World War I, much less the origins of many airpower roles that modern air forces perform today. Even though the author's extensive research may at times overwhelm the reader with detail, the concepts related in the book will appeal to any airpower professional or enthusiast.

4411 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Internal Security Services in Liberalizing States: Transitions, Turmoil, and (In)Security by Joseph L. Derdzinski. Ashgate Publishing (http://www.ashgate.com), Wey Court East, Union Road, Farnham, Surrey GU9 7PT, UK, 2009, 180 pages, $114.95 (hardcover), ISBN 978-0-7546-7504-4.

In a short, scholarly monograph that serves as a cross-cultural case study examining the security regimes and stalled democratic transition between Morocco and Indonesia, Prof. Joseph L. Derdzinski of the US Air Force Academy clearly demonstrates the work done in these two nations (and, more broadly and less deeply, the rest of the developed world). He also addresses the effort that remains, seeking to fill the niche of examining the critical role of internal security systems (like the police, intelligence services, and related institutions) in the process of democratization throughout the world. The study is very technical (but accessible to readers familiar with political science and international relations), meticulously researched, and filled with explanatory footnotes and charts that organize information efficiently.

From the outset, it is clear that *Internal Security Services* assumes the realist perspective, from its approving quotation of Machiavelli that "security for man is impossible unless it be conjoined with power" (p. 3) to its rigorous, detailed examination of the challenges of both Morocco and Indonesia in increased liberalization, given the state of elite power and interests within both countries and the presence of continued terrorist and separatist violence. The introduction examines the state of the literature and identifies the case study's goal of filling a gap by considering the neglected role of internal security forces as a measure of the success of liberalization within a nation. The author then explains his principal approaches and findings. He accounts for the strong focus on two countries by seeking to build a broader conceptual framework for ways that third-party nations and international organizations can effectively encourage liberalization and engender greater respect for personal freedom and human rights as well as leave behind an authoritarian past. Derdzinski offers a detailed assessment of the history and role

4412 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

of internal security forces in Morocco (a nominally constitutional Islamic monarchy) and Indonesia (a nominally secular Islamic democracy with a lengthy history of brutal and corrupt dictatorship) before closing with findings and recommendations for reforming the security sectors of liberalizing nations. These suggestions emphasize enforcement and justice rather than merely legal structure. They also encourage rooting out corruption (through providing a living wage for workers and discouraging moonlighting for police and intelligence officials) and developing a robust civil culture that demands accountability and answerability from security forces for any human-rights violations they commit after the transition from authoritarian rule.

Among the many strengths of this book are its awareness of relevant research, including interviews, periodicals, monographs, and reports about human rights conditions from nongovernmental organizations and the US State Department. The study's concentration on two nations and its broader comparative analysis at the end benefit from both its depth and breadth of approach. The scholarly, technical language may prove a barrier to a general audience, but readers equipped with an understanding of the professional language of political science and international relations will find the book's insights immensely rewarding if they are sympathetic to the realist perspective. The author makes numerous practical recommendations for nations of the West regarding how they might best help other countries in the difficult process of liberalizing and moving beyond "partly free" status. Specifically, he suggests that they honestly wrestle with tensions that arise from the need for truth and accountability from internal security forces and the need for some secrecy and freedom of action on their part to conduct necessary tasks. The latter include preserving the security of the state from threats like secession movements as well as domestic and international terrorism—threats by no means unique to the developing world.

The author's research and findings are of the highest quality and apply to a range of nations far beyond the two cases examined. Derdzinski refers to his own experience in Bosnia as an officer with the North

4413 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Atlantic Treaty Organization, and this reviewer has relevant expertise that confirms the validity of the findings of this research to the nations of Chile and Thailand as well. Clearly, the author's findings and conclusions apply to many nations with stalled democratization in the face of separatist violence, concerns about terrorism, and a lack of commitment to broad-based societal and institutional change that threatens their privileged status and could bring them to justice for past wrongs. The United States has engaged and may yet engage in the process of nation building in several countries across the Muslim regions of the world (e.g., Iraq, Afghanistan, Libya, and Syria). Consequently, the subject of this monograph has considerable relevance to individuals interested and involved in present American military policy as it relates to the Muslim world, especially in light of the democratization of states after the Arab Spring. Well written and exceedingly applicable to our times, *Internal Security Services* offers a scholarly approach to an often-neglected and vitally important aspect of ensuring that postauthoritarian regimes can successfully conform to civilized and democratic norms of behavior. It deserves a wide audience and a fair hearing for its policy recommendations.

Freedom's Forge: How American Business Produced Victory in World War II by Arthur Herman. Random House (http://www.randomhouse.com/), 1745 Broadway, New York, New York 10019, 2012, 346 pages, $28.00 (hardcover), ISBN 978-1-4000-6964-4.

Admittedly, the B-29 fuselage on the cover of *Freedom's Forge: How American Business Produced Victory in World War II* by Arthur Herman caught my eye and led me to scan the first few pages. Thank goodness for slick-looking dust jackets because Herman's book is a page-turner. It is 1939, and Hitler attacks Poland. Soon Britain stands alone. Far away the United States struggles out of the Great Depression. President Franklin D. Roosevelt (FDR) knows that the ocean cannot forever

4414 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

protect America from the chaos engulfing Europe. He decides to prepare via US industrial might, but industry is not all that mighty in the late 1930s. What to do?

The "greatest generation" story of how US industry ramped up to build liberty ships in record time and crank out bombers by the hundreds is probably familiar, at least vaguely, to most people. Herman's book goes deep to tell the story of the men behind that production, shining light on names like Henry Kaiser and others perhaps unfamiliar to Airmen. Wisely, FDR summons and corrals these men, relying on their peacetime métier to make that wartime industrial miracle happen.

And what men they are—the best in their fields: Bill Knudsen and mass production, the aforementioned Henry Kaiser and big construction, and "Cast-Iron Charlie" Sorensen and Ford Auto, to name just a few. Herman explains where these individuals came from and how their American industrial backgrounds—successes and failures—position them to foment brilliant recommendations and tough decisions to get US industry in high gear. It will not be easy; the state of many US industries is dismal. Further, these individuals are human; some simply do not like each other. We witness big egos at play. They clash, on occasion, even to the point of physical violence.

Airpower advocates will find that the book has a certain appeal, simply from the standpoint of how all the airframes such as B-24s and P-51s begin coming out of car factories. Yes, car factories. But be advised that the book focuses on masters of industry as opposed to masters of the air. If one is researching the machinations of, say, Hap Arnold or Jimmy Doolittle in this tale, he or she should note that Herman covers them only slightly. General Arnold's classic book *Global Mission* is the best go-to source for how *A Few Great Captains* played their roles, as described by DeWitt S. Copp in *his* classic work of the same name.

However, one military person does stand out—and rightfully so—albeit briefly. In May 1940 as German tanks traverse France like so many bumper cars, an epochal scene occurs at the White House. Gen

4415 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

George C. Marshall asks FDR if he can have the famous three minutes to give, as Herman appropriately describes it, "the speech of his life" (p. 10). Once FDR grants Marshall the time, the president then receives a stern remonstration to rearm America, and quickly. This is classic "cometh the hour, cometh the man" stuff. Herman captures, perhaps unknowingly, the real pivotal moment that saves America. There is, however, a slight variance with Herman's timing of the event and that of other sources: the author indicates that an urgent telegram from Churchill to FDR, after the fall of France, triggers that meeting; FDR's historical calendar, however, shows Churchill's telegram arriving a day later. This discrepancy, however, is not a detractor. Those, but only a few, lie elsewhere.

For instance, when it comes to the production numbers of tanks, planes, machine guns, and so forth, the book contains a good deal of data—actually, an *incredible* amount of data. The before-and-after numbers are staggering, and a reader may become desensitized to them. Nevertheless, the numbers do work to convey the magnitude of production; they do add to the story's coherence. Also, the creative modular construction of the liberty ships is fascinating, but to a nonengineer, the processes described might be difficult to follow. Readers may need to google terms such as *retractor conveyor* (p. 186) to get a visual idea of this assembly line. A diagram or graphic would have been helpful here. And Herman does not narrate the industrial experts' histories on one timeline. He covers the prominent characters in significant detail, appropriately dedicating a chapter to each. However, readers will have to backtrack to establish who is meeting whom—and when—as their careers intertwine.

Finally, a warning is in order for anyone enamored of FDR and his New Deal. Herman takes aim in an almost iconoclastic way. True enough, prescient FDR eventually brings America's industrial know-it-all men together. But as they undertake the business of industrial conversion for war, they constantly clash with skeptical administration New Dealers who persistently watch, hover, and probe to ensure that big business does not profit too much—never mind that America's sur-

4416 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

vival is at stake. Bill Knudsen, in particular, constantly brushes away inimical bureaucrats as a struggling farmer swats away gnats while racing to finish a harvest ahead of an approaching hailstorm.

Interestingly, one aspect of this saga is not mentioned but inferred. As automakers, dam builders, and clothing manufacturers struggle to accelerate production, they do so without computers, PowerPoint, or any other type of modern cyber convenience. One can almost hear the typewriters clattering away in the background and the screaming into 1930s telephones as monumental problems of factory locations, contracts, material shortages, and worker strikes are sorted out. Perhaps this is instructive for us today: could the United States meet this type of challenge without our modern communications, let alone make it happen *at all*?

No plot spoiler here. History shows that US production capability eventually wins the wars in Europe and the Pacific. Still, Herman writes of these men, their challenges, the obstacles, and crushing deadlines in a way that makes the heart pound.

Hero of the Air: Glenn Curtiss and the Birth of Naval Aviation
by William F. Trimble. Naval Institute Press (http://www.usni.org/navalinstitutepress), 291 Wood Road, Annapolis, Maryland 21402, 2010, 304 pages, $37.95 (hardcover), ISBN 9781591148791.

Hero of the air? Dr. William Trimble's exhaustive biography of aviation pioneer Glenn Curtiss certainly drives the reader to that conclusion. The author offers a thorough study of the aviation pioneer's flying life and his predominant role in the early days of naval aviation. The book is more than the subtitle implies, pointing out that although the Wright brothers were the first to fly, "Curtiss was instrumental in [flight's] development or innovation phase" (p. xiv). As is his practice, Trimble has extensively researched the personal papers of the key

4417 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

players of aviation, official naval documents, period newspaper accounts, and a myriad of secondary sources.

Accompanying the central theme of Curtiss's overall contribution to aviation are several secondary themes, one of which examines the strong partnership between Curtiss and the US Navy: "Early on, advocates of aviation in the Navy, chief among them Capt. Washington I. Chambers, recognized that the Navy had special requirements for airplanes and their operations, and for aviators and their training" (p. xv). Trimble affirms the well-supported position that Chambers utilized Curtiss's unique ability to "design and develop" aircraft along with his experience in experimentation to "meet the Navy's special requirements" (p. xv).

This partnership leads to another secondary theme—that the Navy didn't resist aviation; rather, "the Navy's leadership and bureaucracy adjusted well to aviation and other changes" (p. xv). To support this point, the book discusses at length the Navy's efforts to embrace new technologies, such as long-distance flying, and highlights its desire to conduct the first flight across the Atlantic Ocean, which did in fact occur in 1919. Clearly, the Curtiss-Navy partnership helped add aviation to the Navy's capabilities.

Professor Trimble tells Curtiss's story chronologically, beginning with his family's move to western New York and ending with the death of the aviation pioneer at the age of 52. He portrays Curtiss as an innovative and enterprising man who used a "cut and try" approach rather than a scientific or engineering-based method with everything from bicycles to motorcycles to airplanes. His detailed, almost weekly, accounting effectively relates Curtiss's activities and numerous aviation firsts. Understanding the importance of the often-hostile relationship between Curtiss and the Wright brothers, Trimble includes the substory of their legal battles over aviation patents and their desire to protect their respective business interests.

The author does not place his subject on a throne as the infallible creator of naval aircraft. Rather, he notes that Curtiss's "slack and inef-

4418 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

ficient 'shop' organization had been a source of frustration" to the Navy (p. 189). Throughout, Trimble clearly articulates the negative effect of the cut-and-try approach to aircraft design and Curtiss's lack of an engineering background. Readers learn that after the Navy's successful flight across the Atlantic Ocean in the Curtiss-built NC-4, Curtiss had the "good sense to walk away" from an aviation industry that had outgrown his aeronautical abilities (p. 214). Rather than offer a whitewashed, glossy characterization, this inclusion of the man's shortfalls helps the reader assess his effect on aviation.

As with Trimble's book *Admiral William A. Moffett: Architect of Naval Aviation* (Smithsonian Institution Press, 1994), readers who seek insight into the subject's family life will be disappointed. This is no "there I was" study. Instead, *Hero of the Air* gives us an in-depth look at a key aviation pioneer who had an immense impact on aviation in general and naval aviation in particular. Although Glenn Curtiss was not the first to fly, one cannot deny his critical role in the early days of flight. William Trimble's biography is a must-read for both aviation and naval historians.

Lt Col Dan Simonsen, USAF, Retired
Barksdale AFB, Louisiana

The Royal Air Force in Texas: Training British Pilots in Terrell during World War II by Tom Killebrew. University of North Texas Press (http://www.unt.edu/untpress), 1155 Union Circle no. 311336, Denton, Texas 76203-5017, 2009, 208 pages, $26.95 (hardcover), ISBN 978-1-57441-169-0; $19.95 (softcover), ISBN 978-1-57441-272-7.

In his contribution to the University of North Texas Press's War and the Southwest series, author Tom Killebrew examines a little-known element of the vital and historic "special relationship" forged between the American and British governments during the Second World War. The monograph opens with varied accounts of British wartime hardships and endurance in the face of the widening Nazi political and military advance across Europe. As continental nations fell to Nazi expansion,

4419 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Hermann Göring's Luftwaffe set its sights on Britain during the summer and fall of 1940, subjecting it to the oft-accounted aerial punishment of the Battle of Britain. Although "the Few" of the Royal Air Force (RAF) valiantly halted the German onslaught, flight schools in the British Isles and across the Commonwealth states could not effectively meet the operational demand for pilots in the expanding war. Airspace congestion, notoriously dismal and uncertain isle weather, and austere operational conditions at overseas training locations prevented them from doing so. Given the ever-present risk of raiding German fighter and bomber formations further compounding the problem of fielding effective daily flight training, the RAF had to find a better solution.

The end of 1940 found British military forces girding themselves to repulse the later-abandoned German invasion across the English Channel. Filling the ranks of the RAF took on even more importance during this time since the subject of flight training beyond the confines of the British Empire had become a topic of conversation during the lend-lease discussions held in Washington, DC, in early 1941. Maneuvering around the fading façade of American neutrality, flag-officer luminaries of the US Army Air Forces, US Navy, and a British delegation agreed to host a four-element training scheme for British student pilots in the United States. One of these elements involved the pairing of British training detachments with existing civilian flying-training facilities throughout the American South and Southwest. Thus, the British Flying Training Schools (BFTS) scheme was born, with No. 1 BFTS taking root at the Kaufman County Airport in Terrell, Texas, in 1941.

The Royal Air Force in Texas relates the four-year history of the No. 1 BFTS in meticulous detail, thoroughly describing the school's early days, including site selection, the administrative trials of standing up the new unit, and the logistical challenges of keeping aircraft and pilots flying over foreign soil. The thorough treatment of these subtle contextual details—one of Killebrew's demonstrated strengths as a researcher and author—greatly enhances the story. His inclusion of considerable primary source material enlivens the tale with such comic details as cold-weather flying gear mistakenly provided to initial classes for use

4420 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

during the Texas summer, together with illustrative descriptions of the British cadets' most frequented establishments in downtown Terrell. However, most fascinating are the author's accounts of the nuances of the odd yet very functional command relationship between the on-site British officer cadre and host civilian flight school. Although many individuals in senior RAF circles feared that the cultural and professional divide would make for complications in the execution of vital military training, Killebrew notes the mutual respect and resolve demonstrated by both American and Briton alike. This understanding between aviators became the hallmark of an extremely successful effort to produce top-quality aviators for Britain's first line of defense.

Although the book offers impressive details about the administrative and structural attributes of the No. 1 BFTS, it gives less consideration to the crucial account of the British aviation cadets as individuals. Throughout, Killebrew effectively captures student issues with individual aircraft types, the comedy and tragedy of in-flight incidents, and favored off-duty activities, among other details. For all its strengths, however, *The Royal Air Force in Texas* would have benefited greatly from deeper exploration of the motivations, fears, and personal struggles of the British cadets as they left their loved ones to confront wartime hardships during their rigorous six-month training regimen. That said, Killebrew does not ignore the personal dimension entirely, in that his story includes accounts of cadet interactions at social functions and hospitality visits with Terrell residents, descriptions of the distinctive characters among the 26 total classes of the No. 1 BFTS, and praise of selected graduates' wartime heroics. Further, one must acknowledge that recounting the individual hopes and fears of British cadets was likely hindered by the sheer passage of time, incomplete record keeping by the US government during wartime, and contested claims that structural fires consumed school records in the postwar years.

Despite its isolated shortcomings, *The Royal Air Force in Texas* is an impressive and effective account of the interaction of two seemingly opposite worlds brought together in the name of liberty and embody-

4421 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

ing the greatest tradition of Anglo-American cooperation. By documenting and recounting the events of over 70 years past, Killebrew vividly reminds us of the "special relationship" that still endures, perhaps best captured on the No. 1 BFTS patch: *Mare nos dividit, Set Caela Conjungunt* (what the sea divides, the skies unite).

Capt Walter J. Darnell III, USAF
US Air Force Academy

Liberty's Fallen Generals: Leadership and Sacrifice in the American War of Independence by Steven E. Siry. Potomac Books (http://www.potomacbooksinc.com/), 22841 Quicksilver Drive, Dulles, Virginia 20166, 2012, 184 pages, $15.96 (hardcover), ISBN 978-1-59797-792-0.

Liberty's Fallen Generals is a detailed historical look at a group of generals who gave their lives to the cause of independence during the American Revolutionary War, a conflict laced with stories of the Founding Fathers and other larger-than-life figures. Author Steven Siry paints a picture of these lesser-known martyrs to the cause and shines the light of history onto the significance of their actions and sacrifice. He outlines his purpose in the preface as "a study of generalship, valor, and death" (p. xi) of the 10 men who died in combat from 1775 to 1781, introducing the reader to each general's military background, personal information, and the action that led to his death. Such a method may seem rather mundane, but Siry uses it artfully and masterfully.

His study represents an excellent resource for any serious student of America's foundations. This diverse, interesting group of generals spans the demographic spectrum of the colonies at the time. By presenting each man in chronological order of his death, Siry effectively clarifies the timeline of events—much more so than would a condensation of their lives into an overall history. The index makes the book a useful desk reference while the notes and bibliography lend it authority as they elaborate on general points. Clear citations and the aca-

4422 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

demic source material add to the study's appeal as an important part of any library on the Revolutionary War.

Unfortunately, one finds a significant amount of overlap in the background material for Siry's 10 subjects. Initially, he points out that many of these men were present at the same actions or came from similar origins. Given the set structure used for each of the chapters, reoccurring events appear in multiple sections, increasing the probability of confusing the subjects with each other or, worse, of becoming boring. This practice creates irregularity in the book and abruptness between chapters, making it seem more like a collection of essays on a single subject than an organized study. Nevertheless, *Liberty's Fallen Generals* is a well-done examination of an overlooked but fascinating topic.

Jason P. Smock, MLIS
Saint Paul, Minnesota

The Insurgents: David Petraeus and the Plot to Change the American Way of War by Fred Kaplan. Simon & Schuster (http://www.simonandschuster.com/), 1230 Avenue of the Americas, New York, New York 10020, 2013, 432 pages, $28.00 (hardcover), ISBN 978-1-4516-4263-6; 2014, 432 pages, $16.00 (trade paperback), ISBN 978-1-4516-4265-0.

Fred Kaplan's *The Insurgents*, a *New York Times* best seller, is the most comprehensive account yet of the reframing of American military strategy in Iraq and Afghanistan as counterinsurgency (COIN) campaigns. A masterful storyteller, Pulitzer prize–winning journalist, columnist for *Slate*, and an MIT PhD, the author is well versed in security studies, and in this case he has created a real page-turner. His previous publications include *The Wizards of Armageddon* (Simon & Schuster, 1983), a classic study of nuclear strategists and their theories.

Kaplan argues that David Petraeus and his fellow insurgents succeeded in changing the Army from an institution focused on fighting Cold War–style air-land battles against conventionally equipped uni-

4423 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

formed opponents to a more flexible force prepared to conduct wars among the people. The larger context is an Army that turned its back on COIN after Vietnam even though the United States engaged almost continuously throughout the 1990s in such places as northern and southern Iraq, Somalia, Haiti, Bosnia, and Kosovo. These engagements were euphemistically called military operations other than war (MOOTW). The prevailing ethos among top Army generals about such conflicts was that "real men don't do MOOTW," attributed to Gen John Shalikashvili, USA, chairman of the Joint Chiefs of Staff (p. 45).

Because of this prevailing ethos against MOOTW and Secretary of Defense Donald Rumsfeld's policy of transitioning responsibility as quickly as possible to the Iraqis, the revival of COIN thinking required a revolutionary movement or insurgency within the Army. Its center of gravity was a network of Soldier-scholars who, as captains and majors, had taught in either the Department of Social Sciences ("Sosh") or History at West Point. These officers kept alive the lessons of Vietnam and revolutionary warfare through their teachings. More importantly, they also developed bonds among themselves that would later enable them to become a critical mass for changing how the Army fought in Iraq and Afghanistan.

Authors David Cloud and Greg Jaffe advanced a similar thesis in *The Fourth Star: Four Generals and the Epic Struggle for the Future of the United States Army* (Three Rivers Press, 2009), which featured Gen Peter Chiarelli and Gen David Petraeus as Sosh alums spearheading a more enlightened strategy in Iraq, compared to that of Gen John Abizaid and Gen George Casey, who supported Secretary's Rumsfeld's policy of rapid transition. Kaplan's work picks up on this Sosh connection and expands it to tell a completer story about how the United States changed its strategy in Iraq and Afghanistan.

Kaplan's heroes are the network of warrior-scholars who taught at West Point. They include John Nagl, Petraeus's protégé, who earned a PhD at Oxford where he wrote *Learning to Eat Soup with a Knife: Counterinsurgency Lessons from Malaysia and Vietnam* (University of Chicago

4424 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Press, 2005). His book was widely distributed by the Department of Defense and Army officials as things turned south in Iraq. Nagl would coauthor Field Manual (FM) 3-24, *Counterinsurgency*, 2006, the new COIN manual. H. R. McMaster, another Sosh alum, studied for his PhD at the University of North Carolina where he wrote *Dereliction of Duty: Lyndon Johnson, Robert McNamara, the Joint Chiefs of Staff, and the Lies That Led to Vietnam* (HarperCollins, 1997). The chairman of the Joint Chiefs of Staff, Gen Hugh Shelton, ordered all of the service chiefs to read it. Several other Sosh alums with PhDs, including some with equally impressive publications to their credit, constituted the movement's core.

Kaplan's study shows that the Army's program of sending promising captains to graduate school to earn PhDs followed by instructor duty at West Point has proven a wise investment. The Army seems to have broken the code on how to get these young officers back to qualifying operational assignments so that at least some—Petraeus is a case in point—progress to the top ranks and affect the course of events for the better.

Kaplan portrays Petraeus as a master at bureaucratic politics, which he learned from previous mentors. He adeptly exploited and expanded the Sosh network to include like-minded civilian academics, think tanks, and policy wonks as he orchestrated development of the new COIN doctrine. They became known as "COINdinistas." Kaplan does a remarkable job of tracing their influence as they build momentum for a new campaign strategy. As a result, efforts converge from different quarters supporting the appointment of Petraeus to implement it.

A strength of this work is Kaplan's ability to relate the richness and complexity of the historical case without overwhelming the reader. To his credit, he shows that COIN strategies were already being implemented in Iraq before the troop surge of 2007 and the publication of FM 3-24. McMaster's pacification of Tal Afar demonstrated this fact and set in motion a chain of events that would lead to the Anbar Awakening. The difference when Petraeus took charge, however, was a *campaign* establishing unity of effort on the COIN strategy throughout Iraq.

4425 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Kaplan's identification of the central paradox of COIN campaigns is an important insight. The illegitimacy of the ruling elite causes insurgencies to exist in the first place. Yet, successful COIN campaigns require a legitimate host whose interests coincide with those of the intervener. Although the COIN approach produced stunning results in parts of Iraq and Afghanistan, the goal of stable, legitimate governments has not been achieved. The lesson is that COIN will probably not prove effective when the insurgents are out of reach, the government is too corrupt, or the intervening nation is unwilling to commit resources to a lengthy campaign.

Students of the art of war develop themselves by analyzing cases of challenge and response as well as the relationship between military theory and practice. Kaplan has a writer's knack for crafting these themes in a gripping way. Change begins with ideas and is therefore an intellectual endeavor. As Jimmy Doolittle said, "If we should have to fight, we should be prepared to do so from the neck up instead of from the neck down." *The Insurgents* is an excellent case study about the relationship among theory, doctrine, and institutional change.

4432 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Preface

During the most recent rounds of Base Closure and Realignment Commission activities in 2005, a significant number of training bases were closed. In light of the introduction of new technologies and the great expansion of unmanned aircraft systems (UASs) in the force, Department of Defense planners and some in Congress have become concerned that the existing training infrastructure—bases and their training support facilities—may not be adequate to train UAS air and ground components and the ground forces that use such equipment to capitalize fully on their capabilities. Accordingly, the Deputy Director, Readiness and Training Policy and Programs in the Office of the Under Secretary of Defense for Personnel and Readiness (OUSD [P&R]) asked the RAND Corporation to assess the adequacy of UAS training to support current and future requirements. In addition, the House Armed Services Committee report accompanying the Fiscal Year 2013 National Defense Appropriations Act raised a number of questions concerning training strategies with particular reference to the use of simulators to facilitate training.[1]

This report considers three issues: (1) the development of a general concept for UAS training in the context of current and anticipated future UAS inventories, (2) the development of an appropriate framework based on the general concept to address UAS training requirements, including the appropriate use of simulators, and (3) the airspace requirements necessary for UAS training. The research reported on here covers UASs in the Army, Navy, Air Force, and Marine Corps as fielded and plans as they existed during 2012. A RAND team carried out extensive field visits to understand the current ability of the services to conduct (1) service-specific training and (2) joint training at both home station and joint training facilities. The research will be of interest to those concerned with UAS programs and operations; joint training; or more generally, the incorporation of disruptive technologies into Department of Defense programs and operations.

This research was sponsored by the OUSD (P&R) Directorate for Training and Readiness Policy and Programs, in coordination with the Joint Forces Command's Joint Warfighting Center and the Joint Unmanned Aircraft Systems Center of Excellence. The research was conducted within the Forces and Resources Policy Center of the RAND National Defense Research Institute (NDRI), a federally funded research and development center sponsored by the Office of the Secretary of Defense, the Joint Staff, the Unified Combatant Commands, the Navy, the Marine Corps, the defense agencies, and the Defense Intelligence Community. 4437 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Summary

Unmanned aircraft systems (UASs) have become increasingly prevalent in and important to U.S. military operations. The number of systems has surged, as has the slice of the defense budget allocated to them. Roles have also changed. Initially employed only as reconnaissance or intelligence platforms, they now carry out other missions, including attacking enemy forces. Successful operational tests and demonstrations of the expanded range of UAS capabilities have led to rapid fielding of new systems, often placing unanticipated demands on logistics and training systems and on field commanders to employ new systems effectively. UASs must now be integrated into the training programs of the services. Building a responsive, effective, and efficient UAS training program is a challenge during times of reduced budgets. Any new program must be based on a review of existing training capabilities and new investments across the services.

Focus of this Research

The Deputy Director, Readiness and Training Policy and Programs, in the Office of the Under Secretary of Defense for Personnel and Readiness (OUSD [P&R]) asked the RAND National Defense Research Institute (NDRI) to assess the adequacy of UAS training to support current and future requirements. Proposals to resolve service and joint UAS training issues must be informed by a clear understanding of current problems, opportunities for correction, and associated costs and benefits of the corrections. In this report, we address a number of issues, including (1) a general concept for UAS training; (2) an appropriate framework to address UAS training requirements, including the use of simulators; and (3) the limitations of the infrastructure to accommodate UAS training, including those due to national airspace restrictions. The research considers UASs in the Army, Navy, Air Force, and Marine Corps, both those that are currently fielded and those that were planned to be fielded as of 2012.

Disruptive Technologies and Acquisition Processes

In 1995, Clayton Christensen introduced the term *disruptive technology*, distinguishing it from what he termed *sustaining technology*. In his nomenclature, a sustaining technology improves the performance of an existing system and does not require significant structural adjustments to processes, organizations, or operational paradigms. Disruptive technologies, however, change the way a business operates. The UAS is a disruptive technology.

4439 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

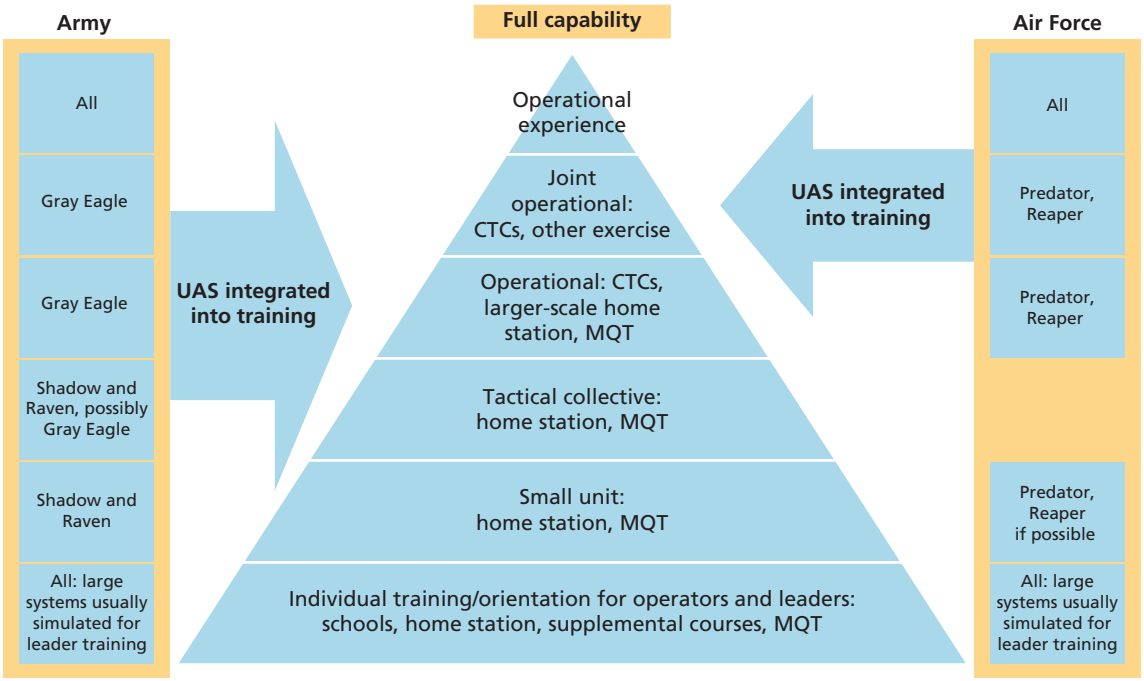
UASs found their way into the force by means of rapid acquisition procedures that were designed to deliver new technologies to the warfighter much faster than traditional procedures could, but often at the cost of not having in place the support these new systems required to become a sustained part of the force structure. Because of the rapid acquisition of these systems, the services have had to rely upon contractor support in ways that are inconsistent with the full and sustaining integration of these systems into service inventories. Such integration starts with the development of an appropriate concept for training.

Training Concepts and Frameworks

We will begin by discussing the general ideas that should guide UAS training—the training *concept*. Then, we will consider how the parts identified in the concept fit together into a conceptual structure for that training—a training *framework* designed to enhance combat power and other operational capabilities.

Joint Operations; Multiservice Tactics, Techniques, and Procedures; and UAS Training

Military operations today are usually referred to as *joint operations*, emphasizing the interdependence of the services. That might lead one to think that joint doctrine; joint concepts of operation; and joint tactics, techniques, and procedures would provide focus for training. Clearly, training does not take place for its own sake; it should be driven by doctrine. In his cover letter to Joint Publication 3-0, 2011, ADM Mike Mullen stated that it established "the framework for our forces' ability to fight as a joint team," but nowhere does it discuss the management of UASs. Moreover, nowhere in any other joint publication is there a grand doctrine for the employment or management of UASs on the battlefield. While the services have agreed to a set of multiservice tactics, techniques, and procedures (MTTPs) to be incorporated into their respective training programs, note the use of *multiservice* rather than *joint*.



At least for the foreseeable future, each service will continue to field UASs and must bring to the fight forces fully capable of operating them and integrating their capabilities into operations. While grand doctrinal issues remain unresolved, common procedures agreed to and trained by the services will remain the foundation on which American military operations must be built. In this way, rather than being the foundation for UAS training, joint operations are the goal of such training, which must be firmly grounded on the UAS training each service gives both its supported and supporting units.

The general concept we advance for UAS training here rests on the notion that the greatest beneficial effect—that is, an increase in the force's operational effectiveness—occurs with a synergy among the UAS platforms, those who operate them, and those who integrate them into combat operations. While the report considers training concepts for ground, air, and sea forces, they share a common framework. Figure S.1 depicts our framework for ground and air forces; the one for naval forces is similar.

The concept underpinning the framework calls for increasing integration of its several parts as the level of training moves up the pyramid. Army systems appear on the left, Air Force on the right. At the bottom, training begins with individual training for operators and leaders, grounding each group in the basics of the system. Training then progresses to the small unit level, which, as with individual training, is largely done at home station. Moving up the pyramid, training occurs at increasingly higher echelons, battalion and brigade. Moving to joint

4440 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Figure S.1
UAS Training Framework

RAND *RR440-S.1*

operations involves Air Force units, which have gone through a similar process of progressive training. They join together in exercises, many of which are conducted at the large combat training centers (CTCs), to integrate close air support and Air Force UASs into the ground maneuver plan.

Assessment of the State of UAS Training in 2012: Service and Interoperability Training and the Role of Simulators

Service Training

Speaking generally, the services have been relatively effective at training the individual skills required to operate and maintain the UASs, although the services differ in their approaches. The Army, which tends to use enlisted personnel to staff its UAS units, has developed courses that award Military Occupational Specialties for the operators and maintainers for its Shadow and Gray Eagle systems. Training for the Raven UAS, which is about the size of a large model airplane and is used to support lower-echelon units, is a unit responsibility carried out through a "train-the-trainer" concept. The Marines use officers who are qualified aviators or aviation command and control officers as pilots, and enlisted personnel operate the payloads. The Air Force pilots are officers and are either rated pilots who graduated from pilot training or UAS-only pilots who graduated from a program designed specifically for flying UASs. Sensor operators for Reaper and Predator are either trained into a new career field or cross-trained from another Air Force Specialty Code. Those for Global Hawk come from the imagery analyst

4441 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

career field. Maintenance personnel come through the Air Force's maintenance education and training programs.

The more challenging part of the training comes at the integration level, where UAS personnel must meld their efforts with those of ground combat units. This occurs within and between services. Integration requires substantial practice under realistic conditions that do not occur frequently. Rotations at a CTC are often the only occasions, short of actual operations in theater, in which commanders face the challenge of integrating all battlefield operating systems at once, and the addition of the UASs necessarily complicates synchronization and integration tasks. Thus, it is not surprising that initial assessments of UASs during integrated training are, at best, mixed.

The key concerns of UAS units tend to be similar across services. For ground and Air Force units, the concerns are beddown and support facilities, airspace limitations, and simulators. Many of the beddown and support issues can be resolved with relatively minor construction. Some airspace issues, however, are not likely to improve. The Navy has airspace issues at specific installations but generally faces fewer restrictions because it can operate outside the 12-mile coastal limit with relative freedom.

Interoperability Training

To date, interoperability training at the National Training Center (NTC) and the Joint Readiness Training Center has been limited. The Government Accountability Office (GAO) has cited two significant challenges for improved interoperability training: (1) "establishing effective partnerships with program stakeholders through comprehensive communication and coordination and (2) developing joint training requirements that meet combatant commanders' needs," with particular emphasis on tactical-level training (GAO, 2005, p. 2).[1] To meet this challenge, the Department of Defense (DoD) established an implementation plan that gives the Office of the Under Secretary of Defense for Personnel and Readiness overall responsibility and the Deputy Under Secretary of Defense for Readiness executive agent responsibility for training transformation planning, programming, budgeting, and execution progress.[2]

While RAND did not assess interoperability training in detail, our discussions with the training community, including trainers at the NTC, suggest that such training opportunities have been limited because Air Force assets, particularly the Predator, have generally been unavailable due to pressing operational requirements in Iraq and Afghanistan. This same general observation was also reported by the GAO (2010b, p. 26). The problem of transiting Air Force UASs from Creech Air Force Base, Nevada, to the NTC at Fort Irwin, California, through Federal Aviation Administration–controlled airspace is often cited. Permanently stationing Air Force UAVs at the NTC, much as the Marine Corps has done by stationing Shadow UAS squadrons at the Marine Corps Air Ground Combat Center at Twentynine Palms, California, to support training there, would of course negate that problem. However, the experience of the Marine Corps suggests that the mere presence of UASs will not ensure

---

[1] GAO, 2005, p. 18, noted that,

> [i]n the past, joint training tasks were primarily focused at the command level and were identified through DOD's authoritative processes that built requirements by translating combatant commander inputs into training requirements. Training transformation has expanded joint training requirements to include those at the tactical level in addition to joint command-level training.

[2] See Director, Readiness and Training Policy and Programs, 2006.

4442 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

that the forces are properly trained. The forces must be prepared for such training at their home stations. In addition, given the common MTTP, forces trained to operate with their own service UASs should find working with UASs from the other services less challenging.

Simulators

Congress has pressed for information on the role simulators might play in a UAS training strategy, seeking an "informed balance between live training and simulated training."[3] But the conditions that make a compelling case for using simulators in the training of fighter pilots are largely absent when it comes to UAS training:

1. UAS flying hours are much less expensive than flying hours for manned aircraft.
2. The kinds of operational activities that need more training emphasis, in particular air-ground coordination, are generally not activities for which simulators per se can substitute for live flying.
3. While simulators are an inherent part of the systems used for initial training of pilots and sensor operators,[4] they are not well suited (and not designed) for training operating forces on the full spectrum of UAS capabilities.
4. At best, simulators complement rather than substitute for live training. Given the current state of the fielding of UAS, first priority must be given to building the live flying infrastructure. Then, and only then, might funds be used to undertake the research and development that must precede any consideration of fielding the kind of interactive UAS air-ground simulators that could train both UAS crews and ground troops.

We concluded that, given current budget limitations and the importance of fully developing the opportunities for live training and the relatively low cost of such training, diverting funds to develop higher fidelity UAS-ground simulators would be unwise at this time. However, the Army's air-ground integration ranges provide a good example of judicious use of simulators to do what simulators do best—in this case, scoring target hits without using expensive live munitions and without blowing up fairly expensive targets. In the future, the services should reevaluate the need for virtual training based on a cost and effectiveness analysis (COEA) that includes developmental costs for simulators, savings based on the costs of flying UASs, and the critical availability of air space for training.

Implications and Recommendations

The Guiding Principle: "Train As We Fight"

DoD has been under some pressure from the Congress and such organizations as the General Accountability Office for the lack of central control and the lack of the development of joint DoD strategy for training. In reality, the services continue to develop UAS training initiatives primarily to meet their own unique requirements, and the opportunity for joint training is limited. Progress has, however, been made with the development of the MTTP and the recognition that interoperability training is a service responsibility. For now, DoD should encourage

[3] See, for example, Chairman, House Armed Services Committee, undated.

[4] See Shawn Johnson, UAS cost per flying hours, personal communication, April 10, 2013.

4443 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

each service to solve its own UAS training problems, not constrain any one service under the guise of joint training. Given strong service programs, there will be ample opportunity to focus on joint training in the future, when the opportunity presents itself. Today, however, the services are still struggling with how to incorporate these new systems. The appropriate strategy for UAS training is to insist that the services train as they will fight. Accordingly, to *train as we fight* in the future, DoD training strategy must

- engender better appreciation of UAS capabilities throughout the chain of command
- address organizational, structural, and infrastructure and support issues
- enable "train as we fight" in collective unit training
- enable "train as we fight" in exercises.

Initiatives with Near-Term Payoff

To accomplish these goals, a number of initiatives should pay off in the near term, including

1. increasing exposure to the capabilities and limitations of UASs
2. harnessing the lessons-learned process to guide the development of service and joint doctrine and tactics, techniques, and procedures
3. addressing well-known but underresourced training infrastructure shortfalls.

Institutionalize Training for UAS Capabilities Over the Longer Term

Institutionalization will require more-general efforts, including

1. acculturation (Many end users do not yet have a well-developed appreciation of UAS capabilities.)
2. development of a cadre of UAS professionals with hands-on experience in all echelons of UAS operation
3. integration of UASs into service force structures
4. adaptation, including
   a. accounting for the evolution of the roles of UASs in the full range of military operations
   b. continuous resolution of UAS doctrinal issues.

Summary of Findings and Recommendations

The findings and recommendations are summarized below:

1. The proper strategy for DoD at this time is to encourage each service to solve its own UAS training problems, rather than to constrain any one of them under the guise of joint operations.
2. DoD should support current and future programs to develop ranges and beddown and support facilities similar to those in the Army's current programs.
3. In spite of the demands of deploying units and sustaining combat operations in Afghanistan, Army trainers indicate that Army units are better at maintaining qualification for Shadows than for Ravens. Nevertheless, not all units have been able to maintain high

4444 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Shadow qualification rates—some units arrive at the NTC with one-half or fewer of their operators qualified.

4. If joint training becomes a priority, the Air Force's current basing and beddown posture will become a problem. The Air Force could consider the location of Army hubs when choosing where to base its UAS fleet. A location that is near Army maneuver elements might make airspace access less of a restriction or at least make certificates of authorization more practical. Proximity might provide more opportunities for training UAS integration throughout the entire mission planning process.
5. Given current budget limitations and the importance of fully developing the opportunities for live training and the relatively low cost of such training, diverting funds to a research and development program to develop higher-fidelity simulators would seem to be unwise at this time.

Path to the Future

This report presents and discusses a multitude of means for setting up UAS training strategies for success, including supporting ongoing facilities and basing initiatives; expanding such facilities, where possible, to enable wider availability of UASs to support collective training; and increasing the use of UASs—the complete UAS package, including joint tactical air controllers and other coordinating elements—in collective training, both local and in larger exercises. We have noted the need to support continuing efforts to resolve airspace access issues, observing as we did so that there are ways to keep such restrictions from imposing serious limitations on much of the UAS training envisioned here. Similarly, we have discussed the potential for simulators to add value in training, now and perhaps more in the future. But we have also cautioned that simulators in their current state are not a good substitute for live use of UASs in collective training.

The path to the future for UAS strategies starts now, with support for ongoing initiatives that will continue the trends toward better training integration, thus improving the ability of end users to employ the multiple capabilities of UASs in their operations. The path continues, using that foundation, with longer-term efforts to add to acculturation of end users, professionalization of the UAS community, and integration of the two to harmonize the capabilities of UASs as key elements of overall force effectiveness.

Acknowledgments

The research presented here is the result of numerous field visits and discussions with members of service and department staffs in the Pentagon, commanders and operations staffs in operational arms of all the services, planners and training developers in service training commands, trainers and staffs at the various combat training centers, students in UAS operator schools, and UAS operators. So many shared information and data and providing thoughtful comments, advice, and insights that it is impossible to single out anyone without possibly slighting someone else. Moreover, the views expressed in this report are our own and should not be attributed to any individual or organization.

We would be remiss, however, if we did not recognize the support we received from Frank DiGiovanni, Director of Training Readiness and Strategy in the Office of the Under Secretary of Defense (Personnel and Readiness), and Joan Vandervort, our project coordinator in Mr. DiGiovanni's Office. Their commitment to developing an appropriate training strategy for UASs was the driving force behind this study.

CHAPTER ONE

Introduction

UASs Play an Increasing Role on the Battlefield

During the last decade, in large part because of the dynamic nature of operations during Operation Enduring Freedom and Operation Iraqi Freedom, recognition of the importance of developing new capabilities to meet the ever-changing threats our military forces face has grown. As a result, the Department of Defense (DoD) has undertaken operational and technology demonstration projects to test new technologies and systems outside the traditional acquisition process. Many of these systems involve unmanned vehicles and some unmanned aircraft systems (UASs). In 2000, the DoD had fewer than 50 unmanned aircraft in its inventory; by 2012, it had more than 7,100, as shown in Table 1.1 (Gertler, 2012).[1] The size of the Department's investment in these systems today similarly dwarfs prewar levels. In 2000, the DoD spent $284 million on UASs, while the 2010 budget for UASs has grown to over $6.1 billion (GAO, 2010a, p. 1). Figure 1.1 shows the growth of UASs from 1988 to 2013. Figure 1.2 shows projected growth in UAS programs as of 2012.

UASs have two main advantages over manned aircraft: They eliminate the risk to a pilot's life, and they provide capabilities not subject to human limitations. They are also cheaper to procure and operate than manned aircraft. While they minimize risk to operational crews, they introduce new complications and hazards not associated with manned aircraft. While some think of UASs simply as a substitute for manned aircraft, UASs increasingly complement manned aircraft, providing new capabilities for the force to utilize. Combined UAS and helicopter operations are but one example (McLeary, 2012).

Originally, UASs were used to gather intelligence. During the Vietnam War, drones flew strategic reconnaissance missions over denied areas. The Israeli Air Force successfully used UASs during operations in Lebanon in 1982 and for many years led the world in developing UASs and tactics for employment. Subsequently, longer-endurance systems introduced the ability to maintain surveillance on distant and moving targets. More recently, UASs originally designed for reconnaissance have been modified to carry precision-guided weapons to attack ground targets, greatly expanding the role such systems play on the modern battlefield. This also has expanded and complicated the training of UAS crews as full participants in the joint and combined arms battle.

Successful operational tests and demonstrations of the expanded range of UAS capabilities have led to rapid fielding of new systems, often placing unanticipated demands on logistics

[1] See Appendix A for descriptions of the major systems.

and training systems and on field commanders to employ the new systems effectively. UASs must now be integrated into the training programs of the services.

4455 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Building a responsive, effective, and efficient UAS training program is a challenge in a time of reduced budgets. Any new program must be based on a review of existing training capabilities and new investments across the services.

Integrating UASs into the core operations of the DoD presents the kinds of special problems that are common when new technologies appear and clash with existing ways of doing business. Such clashes happen frequently enough that there is a term for such innovations: disruptive technologies. The rapid introduction of UASs into operations in operations Enduring Freedom and Iraqi Freedom and the attendant force structure growth have presented just such challenges (as discussed in Chapter Two). The resulting disruption has contributed to lags in the ability of joint doctrine, tactics, techniques, and procedures (TTP) to keep pace and in the ability of joint training[2] and service-specific managers to develop and execute training programs.[3]

Focus and Approach of this Research

The Deputy Director, Readiness and Training Policy and Programs in the Office of the Under Secretary of Defense for Personnel and Readiness asked RAND to assess the adequacy of UAS training to support current and future requirements. Proposals to resolve service and joint UAS training issues must be informed by a clear understanding of current problems, opportunities for correction, and associated costs and benefits of the corrections. In addition, the current extraordinary pressures on the overall federal budget, including the defense "top line," and the ongoing review of U.S. strategy will likely have implications for force structure and basing, resulting in a number of yet-unknown factors that could profoundly affect the future of UAS programs. These uncertainties notwithstanding, a number of issues must be addressed: (1) a general concept for UAS training; (2) an appropriate framework for addressing UAS training requirements, including the use of simulators; and (3) the airspace requirements necessary for UAS training.

The research reported on here covers UASs in the Army, Navy, Air Force, and Marine Corps as fielded and plans as they existed in 2012. Because of the increasing use of these unmanned systems to support to ground operations, the RAND effort has more closely examined the interface between UASs and operating elements of ground forces. To this end, a team from RAND carried out extensive field visits to understand the current ability of the services to conduct (1) service-specific training and (2) joint training at both home station and joint train-

---

[2] Department of Defense Directive 1322.18, January 13, 2009, defines joint training as "Training, including mission rehearsals, of individuals, units, and staffs using joint doctrine or tactics, techniques, and procedures to prepare joint forces or joint staffs to respond to strategic, operational, or tactical requirements that the Combatant Commanders (CCDRs) consider necessary to execute their assigned or anticipated missions."

[3] Chairman of the Joint Chiefs of Staff Instruction 3500.01G, March 15, 2012, p. C-2, defines service training as follows:

> Service Training: Service Active Component (AC) and RC training (including USSOCOM) is based on joint and Service policy and doctrine. Service training includes basic, technical, operational, and interoperability training to both individuals and units in response to operational requirements identified by the CCDRs to execute their assigned missions.
>
> Joint Training. Training, including mission rehearsals, of individuals, staffs, and units, using joint doctrine and tactics, techniques, and procedures, to prepare joint forces or joint staffs to respond to strategic, operational, or tactical requirements considered necessary by the CCDRs to execute their assigned or anticipated missions.

4456 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

ing facilities. Members of the team interviewed officials involved with UAS training operations at the following Army, Navy, Air Force, and Marine installations and units:

- Beale Air Force Base (AFB), California
  - Global Hawk operations and Distributed Common Ground Station 2
- March Air Reserve Base (ARB), California
  - Air Force National Guard Ground Control Station school
- Holloman AFB, New Mexico
  - (Air Force Predator and Reaper training)
- Fort Irwin, California
  - (Air Force training support unit and selected individuals from the operations group)
- Creech AFB, Nevada
  - (the Joint Unmanned Aircraft Systems Center of Excellence and the operational UAS wing)
- Fort Rucker, Alabama
  - Training and Doctrine Command (TRADOC) capability manager for UASs
- Fort Huachuca, Arizona
  - TRADOC Capability Manager for Intelligence Sensors and the UAS Training Battalion
- Fort Benning, Georgia
  - Maneuver Center of Excellence
- Fort Campbell, Kentucky
  - 101st Airborne Division (Air Assault)
- Marine Corps Base Twentynine Palms, California
  - Marine Corps Air Ground Combat Center (MCAGCC) and two of three active U.S. Marine Corps (USMC) UAS squadrons
- Naval Air Station Patuxent River, Maryland
  - Naval Air Systems Command (Navy and Marine Corps)
- Fort Eustis, Virginia
  - TRADOC Capability Manager for Live Fire Training, Army Capabilities Integration Center, and TRADOC G-3
- North Island Naval Base, San Diego, California
  - Commander, Naval Air Forces.

In addition, the RAND team had extensive discussions with the strategy and planning staffs at U.S. Pacific Command (PACOM) and U.S. Navy Pacific Command concerning rapid acquisition of new technologies, such as the UASs reported on here. In that process, the RAND team gained important insights into the challenges the services face, first in identifying new or disruptive technologies and then in using operational demonstrations or experiments to understand and develop the changes to operational concepts that these technologies would drive.

During these visits, the RAND team talked with operators and support personnel; those who train operators and associated members of the team; those who train and observe the forces that employ UASs in their operations; staff elements concerned with the planning and resourcing of training, both for UAS operators and for the force more generally; and those concerned with the ongoing development of doctrine and concepts of operations for UASs, including their integration into operations.

4457 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Plan for the Report

Chapter Two starts the report with a discussion of disruptive technologies, rapid acquisition processes, and the challenges the DoD faces in integrating UASs into the operations of the military departments. Chapter Three presents a general concept and a framework for training focused on the integration of UASs into military operations. Using the framework, the assessment in Chapter Four considers the current ability of the services to conduct service-specific training at both home station and joint training facilities. This includes a compilation of observations and insights largely gained during our visits to the bases listed above, with our interpretation of their implications for the specification and resourcing of training strategies. Finally, Chapter Five summarizes our research and looks toward the evolving training strategy for DoD in the future. The appendixes present additional material, including a description of ongoing systems, a further discussion of the Defense Acquisition System (DAS), UAS descriptions, and infrastructure considerations and the results of a RAND assessment of training infrastructure.

4458 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

CHAPTER TWO

The Case for and Implications of Unmanned Aircraft Systems Being a "Disruptive Technology"

Over decades, DoD has developed a structured and deliberate approach for the way it acquires new systems, which is formalized in the DAS and the 5000 series of DoD instructions. However, the exigencies of recent military operations have led DoD to develop new technology and acquire and field new systems without going through the steps the defense acquisition process generally requires. While near-term requirements drove such acquisition decisions, these decisions have long-term consequences. Rapid acquisition without a fully developed plan for how the new systems will be sustained over time may well diminish operational effectiveness. A potent example of such an effect is the extent to which the rapid and large-scale introduction of UASs has outpaced investments in the training infrastructure necessary to support the associated operation and maintenance. In the future, personnel will not be able to use or maintain the new systems properly. The Defense Science Board (DSB) made this point forcefully in 2003: "(1) military proficiency is as dependent on the warriors who operate weapon systems as it is on the weapon system technology, and (2) a superb way to waste personnel or system acquisition money is to ignore training" (DSB, 2003, p. 2). Despite the inefficiency of poorly coordinated investments, the DSB found that "systems continue to be created and then fielded with little consideration for the costs that must be incurred during the life cycle to train the weapon's users" (DSB, 2003, p. 44). As it turns out, the difficulty of incorporating new technologies into existing operations and processes is not unusual. It happens frequently enough that there is a term for such innovations: *disruptive technologies*.

The Disruptive Technology Experience in the Business Community

Clayton Christensen introduced the term *disruptive technology* in 1995. He distinguished disruptive technology from what he termed *sustaining technology*. In his nomenclature, a sustaining technology improves the performance of an existing system and does not require significant structural adjustments to processes, organizations, or operational paradigms. Disruptive technologies, however, change the way a business operates (Govindarajan, Kapalle, and Daneels, 2011).

Since the concept was first introduced, a number of studies have focused on ways that enable an organization to incorporate disruptive technologies. Christensen found that many organizations fail to meet the challenges disruptive technologies pose because they focus only on costs and not on how the new technologies change business processes and create new values for customers (Christensen and Overdorf, 2000). As Christensen used the term, *pro-*

4459 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

cesses include the coordination, communication, decisionmaking, and interaction patterns that transform resources into a product. Under normal conditions, processes are stable. They are designed not to be easy to change, and this inertia can impede the adoption and exploitation of emerging disruptive technology (Looy, Martens, and Debackere, 2005). Tellis makes the point that, given limited resources, investments in unfamiliar technologies with unproven returns are opposed because they are seen as "cannibalizing" both resources and customers from established products (Tellis, 2006). Because it is often difficult to introduce such new technologies into existing business units, much of the literature discusses how "spinout" organizations were created to nurture these new technologies (e.g., Henderson and Clark, 1990). For example, in a study of several game-changing technological developments, te Kulve and Smit, 2010, found that successful new product lines usually had a "champion" with "dedicated change strategies" to further the introduction of disruptive technologies.

Unmanned Aircraft Systems: A Case of Disruptive Technology for the Department of Defense

Although DoD operates in a different environment with different incentive structures from those of the business community, it is not immune to the difficulties disruptive technologies have introduced in the private sector.[1] From DoD's perspective, a technology is disruptive when it has the potential to alter the scope and effectiveness of military operations dramatically and is applied in sufficiently large numbers that it can no longer be supported in the same manner as during its initial development (i.e., the military must incorporate its support into its standard logistics and training systems). The UAS qualifies as a disruptive technology on multiple counts. First, as Christensen notes, the advent of the UAS changed the way the U.S. military operated, that is, its "business processes" changed. Second, UASs have broadened the scope of military operations substantially and greatly enhanced the effectiveness of both intelligence processes and strike operations. Finally, they have arrived in sufficient numbers that they now need to be integrated into the standard processes.

As the U.S. went to war in Afghanistan and Iraq, concern grew about the lack of speed and responsiveness in the traditional process for getting new systems into the hands of warfighters.[2] Critics complained about bureaucratic processes that make the traditional system too slow and too risk averse to acquire and field effective solutions rapidly.[3] As late in the conflicts as 2008, Secretary of Defense Robert Gates expressed frustration with the defense bureaucracy, arguing "we must not be so preoccupied with preparing for future conventional and

[1] There are numerous examples of disruptive technologies and how they displaced formerly dominant technologies in both the private sector and the military: Just a few examples are commercial airlines displacing passenger trains, internal-combustion-engine vehicles replacing horse-drawn vehicles, aircraft carriers replacing battleships as the Navy's capital ship, and tanks replacing cavalry.

[2] Appendix B describes DoD's traditional acquisition system.

[3] For example, Lt. General Robert P. Lennox, the Army's Deputy Chief of Staff for Programs and Resources, explained, "This is one of our most common topics of conversation: How do we rapidly field capabilities when technology advances so quickly?" (quoted in Erwin, 2010).

4460 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

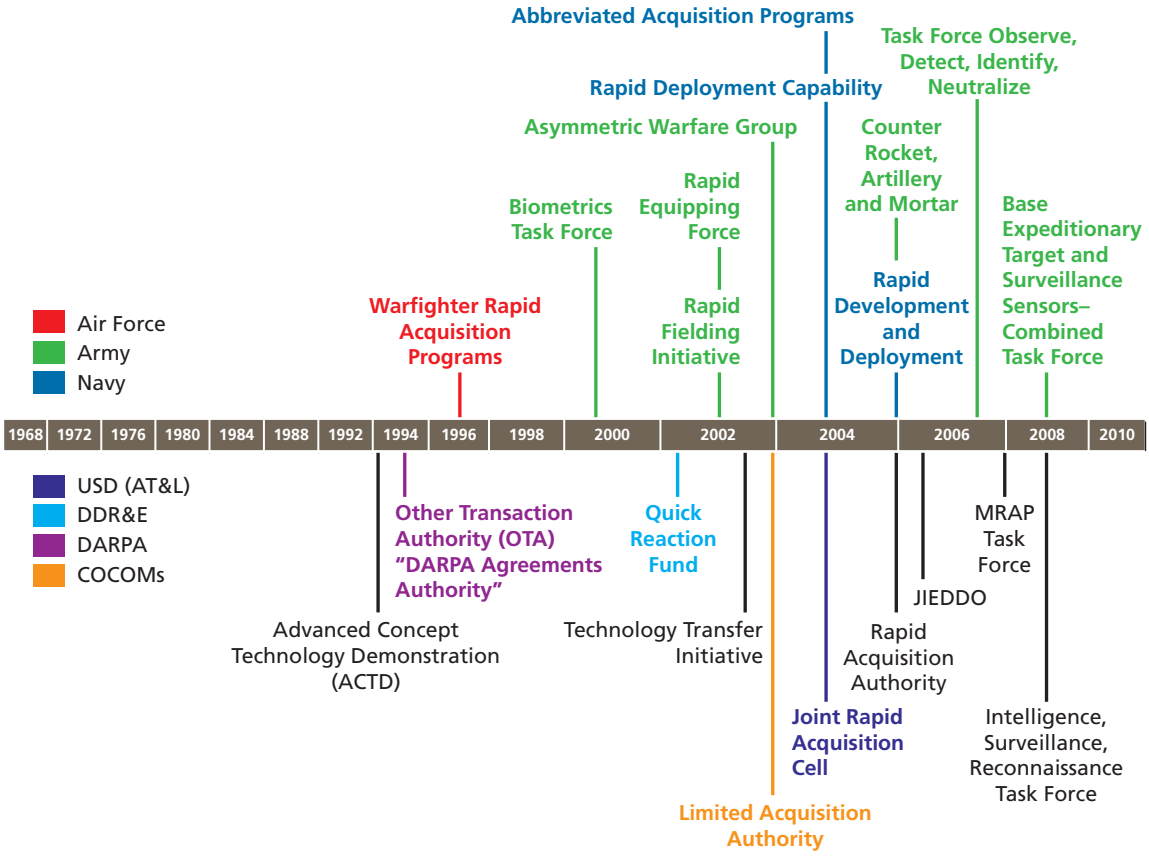
strategic conflicts that we neglect to provide both short-term and long-term all the capabilities necessary to fight and win conflicts such as we are in today."[4]

A Challenge to the Traditional Acquisition System

The virtues of the deliberate and structured traditional acquisition system must be weighed against the fact that the system can take years to field new capabilities. From requirements generation through the DAS and the Planning, Programming, Budgeting, and Execution (PPBE) process, the traditional acquisition system generally takes several years to meet materiel warfighter needs; some systems can take decades (GAO, 2010b). While this long time frame makes some sense for large and complex programs of record, it poses a significant challenge when required capabilities are needed more quickly or are focused more narrowly. This lack of responsiveness has led some observers to argue that the traditional system is not optimized for delivering the full spectrum of desired capabilities. While the system should, in theory, be adaptable for both small and large acquisition programs, it works best in practice for major defense acquisition programs. However, much recent acquisition activity has not been in the form of large programs of record that entail the institutional backing necessary for proper sustainment strategies. The fast rate and large volume demanded for unfamiliar technologies, in particular, have strained the system and pressured traditional acquisition relationships to change.

Rapid Acquisition Programs Met the Challenge

To meet an urgent demand to incorporate new technologies, a series of acquisition processes was created outside the traditional acquisition process and was unencumbered by the prior restrictions designed to mitigate cost, capability, and schedule risk. Unfortunately, while these "workarounds" fostered the fielding of numerous systems, they generally neglected to provide for the institutional sustainment—training and logistical support—needed to facilitate introducing these systems into the force on any basis other than as technology demonstrations. Figure 2.1 captures the proliferation of a selection of these rapid acquisition processes. Below, we discuss several of the more important ones.



Advanced Concept Technology Demonstration

In 1994, in response to recommendations from the Packard Commission and the DSB, DoD introduced the advanced concept technology demonstration (ACTD) (Drezner, Sommer, and Leonard, 1999, p. 23). The Global Hawk UAS, which has found broad applicability in the wars in Iraq and Afghanistan, began as an ACTD. This approach to technological development was intended to improve speed and promote innovation by limiting acquisition hurdles. A system designated as an ACTD could use streamlined management and had reduced oversight requirements (Drezner, Sommer, and Leonard, 1999, p. xiv). ACTDs were intended to bridge the innovation-adoption gap by existing somewhere beyond demonstration of technical feasibility without quite yet becoming major defense acquisition programs. Toward the same end of nudging innovation and eliminating procedural hurdles, in 1994 the National Defense

[4] Gates' distinction reflects what is often a difficult balance between short- and long-term requirements and planning horizons. This creates an institutional tension that has, for example, made the military departments resistant to prioritizing the acquisition of unmanned technology that had near-term applicability but that was not intended to be part of a longer-term vision. See Gates, 2008.

RAND *RR440-2.1*

Authorization Act introduced an authority that allowed the Defense Advanced Research Projects Agency (DARPA), long seen as a mechanism for moving innovative ideas toward materiel solutions, more flexibility in contracting; facilitated use of commercial practices; and waived certain Federal Acquisition Regulations (FARs) and other laws (Drezner, Sommer, and Leonard, 1999, p. 27).

Limited Acquisition Authority

In time of war, new requirements arise that the long and deliberate acquisition system is ill suited to meet. As a result, both Congress and DoD's civilian leadership put in place ad hoc arrangements to seed the development and fielding of new systems. In fiscal year (FY) 2004, Congress granted the Secretary of Defense the authority to delegate a limited acquisition authority (LAA) to Joint Forces Command (JFCOM) to speed the research and development and limited fielding of new systems (GAO, 2007a). However, LAA is an authority, rather than a program, and does not translate into budgeted funds.[5] In the first three years of the authority,

[5] JFCOM had to reallocate funding from its own budget or gain funds from another DoD organization. Over one-half the programs JFCOM supported came from its own budget. In addition, after the systems were acquired, funds were not

4462 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

JFCOM used the LAA to support six projects. After that, LAA activities slowed significantly, a trend GAO suggests may be linked to lack of access to funding (GAO, 2007a, p. 3).

Joint Rapid Acquisition Cell

The Joint Rapid Acquisition Cell (JRAC), also established in 2004 by the Deputy Secretary of Defense and organized in the Office of the Under Secretary of Defense for Acquisition, Technology, and Logistics, constituted another rapid acquisition program. The intent of this cell was to meet new requirements that the combatant commanders (COCOMs) identified as operationally critical; the COCOMs' prominent role in JRAC has led some to tag it the "COCOM's acquisition process" (Middleton, 2006, p. 19; see GAO, 2010b, p. 1). During its initial three years, JRAC supported 24 programs, at a cost of $335.5 million.[6] These funds came primarily from war supplemental appropriations and were not part of the military departments' programs or budgets. A 2009 DSB report found that this meant that "these programs continue to lack serious institutional commitments; very little is being built into the service or other DOD budgets for these programs" (DSB, 2009, p. 6). While JRAC required a life-cycle plan as part of the acquisition process, the DSB found this planning inadequate. Training relied more "on learning on the job with little emphasis on support, training, and sustainment." (DSB, 2009, p. 6). The typical institutional support in the services that is needed to fund, for example, investments in the training infrastructure does not exist for every rapidly acquired system.

Rapid Equipping Force

In 2002, the Army established the Rapid Equipping Force (REF), whose mission was to equip operational commanders with technological solutions to urgent war needs in no more than six months (DSB, 2009, p. 12). In 2005, the REF was made permanent (Kennedy, 2006, pp. 43–45). The organization began with a staff of 14 personnel, which expanded to 150 by 2007 (Dietrich, 2007, p. 5). In 2005 alone, it purchased more than 20,000 items, including robots, surveillance systems, digital translators, and weapon accessories (Dietrich, 2007, p. 6). The REF supported the rapid acquisition and fielding of a widely adopted technology called PackBot, which became a vital tool in the identification and defusing of deadly improvised explosive devices. The REF also supported other unmanned and robotic technology, including the development of the battery-powered, hand-launched, and camera-equipped Tactical Mini Unmanned Aerial Vehicle (UAV) in 2005. The REF project leader described that UAV as a technology that allowed soldiers to "go into situations knowing what's in front of them" (Ainsworth, 2005). REF purchased the mini-UAV commercially and, after some software modifications, quickly had it ready for theater operations (Miles, 2005). Yet, insufficient consideration for back-end support reportedly plagued early REF efforts, and steps have been taken to ameliorate the difficulties. COL Gregory Tubbs, REF director, conceded that the early ad hoc "wild west" days of REF logistical support were a challenge (Kennedy, 2004).

---

readily available for long-term sustainment. A 2005 report from the Center for Strategic and International Studies called for providing rapid acquisition approaches with more-secure funding: "Urgent requirements will be met much faster if they can be resourced without taking funds from existing programs" (Murdock and Flournoy, 2005, p. 98).

[6] The process begins when a COCOM identifies and validates an urgent operational needs statement (or a joint urgent operational needs statement for joint requirements), defined as "urgent, combatant commander-prioritized operational needs that, if left unfilled, could result in loss of life and/or prevent the successful completion of a near term military mission." *Immediate warfighter needs* were the urgent operational needs statements certified as requiring a solution in 120 days or less. For a given system, JRAC is authorized to expend $365 million in research, testing, development, and evaluation funds and up to $2.19 billion in procurement. See GAO, 2007a, p. 12.

4463 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Intelligence, Surveillance, and Reconnaissance Task Force

The high value placed on UASs, specifically in new intelligence, surveillance, and reconnaissance roles, can be seen in the robustly funded Intelligence, Surveillance, and Reconnaissance (ISR) Task Force, which supported the fielding of numerous unmanned systems. In spring 2008, Secretary Gates established this task force to expedite the fielding of ISR assets to combat areas (Sherman, 2008). The task force originally had a 120-day charter; two years after the task force's founding, the secretary announced that it would become a permanent part of the Office of the Under Secretary of Defense for Intelligence (Bennett, 2010). Its mission was to address unmet ISR requirements and to rapidly acquire and field capabilities by coordinating activities and pursuing innovative solutions (Loxterkamp, 2010). The ISR Task Force was to recommend ways to maximize the availability of systems in the inventory and to boost acquisition of additional systems (Best, 2010, p. 17). In FY 2008 alone, Congress approved the reprogramming of $1.3 billion based on ISR-TF recommendations (GAO, 2008b). Among the systems the task force supported were the Navy's unmanned MQ-8 Fire Scout and the fielding and sustainment of 50 unmanned Predators.

Informal Approaches to Rapid Acquisition

The formal approaches highlighted above support rapid acquisition in a variety of ways. Some consist of an acquisition authority but no money (LAA); some consist of funding (REF); some facilitate stronger requirements inputs (JRAC); and some, like Special Operations Command (SOCOM), have everything. Yet importantly, some rapid acquisition has taken place outside even these ad hoc institutional arrangements. For example, in one case, the personal relationships enabled rapid acquisition of command and control (C2) systems. In another, ADM James Stavridis instituted a "culture of innovative thought" into U.S. Southern Command (SOUTHCOM) by developing his own in-house technical capabilities through a process he called Linking Plans to Resources, an approach aiming to associate capabilities with specific solutions (Hicks, 2008, p. 33). He chartered the Joint Innovation and Experimentation Directorate, tasking it with improving how the command trains, fights, and does business (Stavridis, 2010, p. 177). This small innovation staff was to "research, explore, and test emerging technologies available commercially or through Federal research centers" (Stavridis, 2010, p. 89). The directorate was to take the lead in identifying new and creative ways of meeting the command missions, and was given the primary responsibility for "developing validated solutions into an initial operational capability," materiel or nonmateriel (Stavridis, 2010, pp. 178–179). These innovations, looking for better ways to link requirements to resources and developing in-house capabilities for acquiring solutions, reflected new acquisition roles.

PACOM's version was the Plans to Resources to Outcomes Process, which helped in the development of the command's integrated priority list. PACOM also developed its own in-house means of meeting requirements (Murdock and Flournoy, 2005, p. 40). PACOM's Joint Innovation and Experimentation Division uses the integrated priority list to develop rapid, innovative solutions for filling the gap and injecting them into PACOM exercises. Similarly, in 2009, U.S. European Command appointed a special assistant for innovation and technology to field equipment for the war in Afghanistan. Navy Captain Jay Chestnut, special assistant in charge of the project, explained that European Command "knows that 'big acquisition' [the traditional system] is trying to do the right thing but sometimes you need someone working on the side, looking innovatively" (Francis, 2009).

4464 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

In addition to the development of in-house approaches, informal rapid acquisition has also involved forging relationships between the COCOMs and technical expertise outside the military departments. As described by Stavridis, SOUTHCOM worked to both build in-house staff and forge relationships with a "technological base" external to the organization. He highlights, in particular, the partnership with DARPA, in which DARPA pursues "exploration and technology where risk and payoff are both very high, and where success may provide dramatic advances" to the SOUTHCOM mission (Stavridis, 2010, p. 89). Included in Admiral Stavridis' list of outcomes of this productive symbiotic relationship with DARPA are unmanned aerial craft and unmanned surface vessels.

The Use of Fast Track Authorities Can Cause Problems

For acquisitions to be "rapid," certain aspects of the traditional acquisition process have been left out. In many cases, it is the training and support planning that have been omitted. In 2008, the GAO reported that the

> rapid fielding of new systems and the considerable expansion of existing Air Force and Army programs has [sic] posed challenges for military planners to fully account for UAS support elements, such as developing comprehensive plans that account for personnel and facilities needed to operate and sustain programs." (GAO, 2010a, p. 37)

Because many of these programs do not pass through the system development and demonstration phase or a logistics supportability analysis, the data needed to generate training and support planning and ultimately guide investment decisions are unavailable. In 2010, the GAO found that the Air Force had not developed a servicewide plan that identified the number of personnel to be trained, the specific training required, and the resources necessary to establish a dedicated UAS training pipeline (GAO, 2010a). The Air Force has reportedly been struggling to staff significant increases in unmanned systems (Baldor, 2010). Going from a handful of drones in 2007 to 45 by 2010, with plans to operate 50 by 2011 and 65 by 2013, had created significant resource challenges for the department. These resource challenges became heavily pronounced with the "surge" in UAS requirements for operations in Libya and Afghanistan beginning in March and extending into summer 2011. The Air Force, to fulfill combat air patrol (CAP) requirements, stood down a portion of its formal training structure to form three CAPs (U.S. Air Force, 2011). As the Air Force's Deputy Chief of Staff for Operations, Plans, and Requirements explained in 2010, the "number one manning problem in our Air Force is manning our unmanned platforms" (Baldor, 2010).

The GAO similarly found that the Army's personnel authorizations were insufficient to support UAS operations. The Army has determined on at least three separate occasions since 2006 that Shadow UAS platoons did not have adequate personnel to support the near-term and projected pace of operations (GAO, 2010a). Officials from seven Army Shadow platoons in the United States and Iraq told the GAO that approved personnel levels for these platoons did not provide an adequate number of vehicle operators and maintenance soldiers to support operations (GAO, 2010a). Army officials told the GAO that currently approved personnel levels for the Shadow platoons were based on planning factors that assumed that the Shadow would operate for 12 hours per day with the ability to extend operations to up to 16 hours for a limited time (GAO, 2010a). However, personnel with these platoons told the GAO that UASs in Iraq routinely operated 24 hours per day for extended periods (GAO, 2010a). Army officials

4465 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

also reported that combat brigades and divisions require additional personnel to provide UAS expertise to assist commanders in making effective use of new technological systems (GAO, 2010a).

UASs exemplify the challenges of integrating training and sustainment considerations outside the strictures of the formal acquisition process. Ad hoc rapid acquisition processes were able to field UASs rapidly, but because of the nature of these processes, the fielded UASs lacked sustainable institutional support and funding needed for future investments in the training infrastructure. Frequently, the services try to sustain and support these programs by relying on contractors, just as they did during system development.[7] Of course, employing contractors to provide training is not in itself a problem. But it does reflect the extent to which training has been more about expediency than about effective institutionalization, particularly with regard to the imperative to train as we fight and the need to fully appreciate the need to integrate UAS training across the full spectrum of combat units.

[7] For example, the Air Force continues to rely on contractors to perform a considerable portion of UAS maintenance. For example, contractors perform approximately 75 percent of organization-level maintenance requirements for the Air Combat Command's Predator and Reaper UASs. See GAO, 2010a.

4466 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

CHAPTER THREE

Training Concept and Framework for Unmanned Aircraft Systems

We will begin by discussing the general ideas that should guide UAS training—the training *concept*. Then, we will consider how the parts identified in the concept fit together into a conceptual structure for that training—a training *framework* designed to enhance combat power and other operational capabilities. Note that the term *UAS* can be misleading. In fact, there is not a single UAS but rather a family of aircraft that share the common feature that they fly without a pilot on board.[1] These aircraft have very different personnel and training requirements. The vast majority of UASs support ground operations, and that will be our primary focus. As noted in Table 1.1, ground forces—the Army and Marine Corps—own many of these systems themselves, but the Air Force owns some of them and often flies them in support of ground operations. UASs are sometimes flown in support of conventional ground operations and sometimes in support of special operations. Our main focus is on support of conventional forces. UASs are now also being developed that will support maritime forces, and we also consider them.

Training Transformation, Joint Doctrine, Joint Operations, and UASs

Large military operations today are usually joint operations requiring and emphasizing the interdependence of the services. It follows naturally that joint doctrine, joint concepts of operation, and joint TTP would provide focus for training. Accordingly, the DoD's Training Transformation Implementation Plan requires that in order to "improve joint force readiness" there be a "unity of effort in training across Services, agencies and organizations."[2] That said, joint training guidance and publications generally provide guidance direction on the coordination and collaboration among elements of different services to optimize the joint employment of their various capabilities, and not on the employment of any one, specific system or even family of systems, such as UASs.

Clearly, training does not take place for the sake of training; it should be driven by doctrine. Thus, in line with the general focus described above, JP 3-0 (2001) "establishes the framework for our forces' ability to fight as a joint team," but nowhere does the document discuss the management of UASs or any other specific system. Moreover, nowhere in any other joint publication is there a grand doctrine for the employment or management of UASs on

[1] In 2014, the Air Force republished its vision for its system, replacing the term *unmanned aircraft systems* with the term *remotely piloted aircraft* (RPA) (U.S. Air Force, 2014, p. iii).

[2] See Director, Readiness and Training Policy and Programs, 2006, p. 5.

4467 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

the battlefield. However, the services have agreed to a set of TTP to be incorporated into their respective training programs. They describe these as a "multiservice" rather than a joint TTP, thereby avoiding doctrinal issues on how to deploy and manage UAS even as the services support joint operations.

Air Force Maj David Buchanan explored the difficulty of developing a joint doctrine for UASs in a 2010 Naval War College paper, summing up the difference this way: The Air Force believes in centralized control, and the Army believes in decentralized operations. He noted that the

> Air Force's proposal to assume executive agency for all medium- and high-altitude UASs in March 2007 was an attempt to establish unity of command and increase UAS efficiencies. … The Army's position … was that a single-service approach to UAS employment would infringe on the effectiveness of UASs in combat.
>
> The Air Force's centralized approach may result in a more efficient allocation of limited UAS assets, but that efficiency comes at the cost of combat effectiveness. The Army's answer to regain effectiveness has been to decentralize command and control for its unmanned aircraft systems. Ground commanders rely on UASs to provide timely, relevant, and useful intelligence without the lengthy processing and dissemination associated with the Air Force's centrally controlled, theater-wide assets. The Army's Training and Doctrine Command noted that the joint (CAOC [combined air operations center]) solution to meeting the high demand for these low-density assets has been ineffective, arguing against relying on the JFACC [Joint Force Air Component Commander] for UAS coverage. (Buchanan, 2010, p. 7).

JP 3-55.1 reflects a more service-centric notion of jointness.[3] When it was written in 1993, UASs were primarily thought of as reconnaissance, surveillance, and target acquisition (RSTA) assets. As envisioned then, mission planning was to be "based on the requirements of the supported unit," with due consideration for "airspace management conflicts" (JP 3-55.1, 1993, p. II-9).

Over time and with practical experience in Iraq and Afghanistan, the utility of UASs has expanded from consisting primarily of ISR to include armed surveillance and armed overwatch (e.g., for movement support and area security), targeting, communications support, attack, strike, and engagement; in the future, it will further expand to encompass logistical support and casualty evacuation missions. This expanded range of missions presents a challenge that was addressed in 2011 with the publication of a common set of multiservice TTP (MTTP).[4] Each of the four services has agreed to incorporate the MTTP into its respective training. The agreed-to MTTP document requires that

---

[3] JP 3-55.1, 1993, p. II-1, states that the

> [p]rimary mission of UAS units is to support their respective Service component commands as a tactical RSTA system providing the commander a capability to gather near-real-time data on opposing force position, composition, and state of readiness. However, as is the case with all assets and groupings within the joint force, the joint force commander (JFC) has full authority to assign missions to and task component UAS to conduct operations in support of the overall joint force.

[4] Reflecting the multiservice, rather than joint, nature of the document, each service has assigned its own number to it: Army Tactics, Techniques and Procedures 3-04.15, Marine Corps Reference Publication 3-42.1A, Navy Tactics, Techniques and Procedures 3-55.14, and Air Force Tactics, Techniques and Procedures 3-2.64. From here onward in this report, we will refer to the document simply as "the MTTP."

4468 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

> group 3-5 UAS operations will be coordinated with the ACA (airspace control authority) and included in the ACO (airspace control order), SPINS (special instructions) and the ATO (air tasking order) in order to separate UASs from manned aircraft and to prevent engagement by friendly air defense systems. (MTTP, 2011, p. 12)

Table 3.1 describes the five UAS groups. The TTP for UASs that the services agreed to recognize that UASs may either be controlled by a centralized or joined C2 node (MTTP, 2011, p. 15) or be operated independently and that the service component commander may retain operational control of UASs (MTTP, 2011, p. 16), thereby avoiding the doctrinal issue that divided the Army and Air Force. In general, UAS control during the execution of an operation should be at the lowest tactical level to streamline the decision time lines and thus optimize responsiveness. The MTTP provides vignettes to help supporting and supported units understand how to incorporate and use available UAS assets more effectively. It should also be noted that no distinction is made between organic and nonorganic UAS support (MTTP, 2011, p. 40).

At least for the foreseeable future, each service will continue to field UASs and must bring to the fight forces fully capable of operating these aircraft and integrating their capabilities into joint operations. While some overarching doctrinal issues remain unresolved, the common procedures the services have agreed to and train for will remain the foundation on which UAS operations must be built, just as they are for military operations more generally. In this way, rather than being the foundation for UAS training, joint training is the apex of such training, which must be firmly grounded on the UAS training each service gives both its supported units and the supporting UASs.[5] This is the main focus of this report.

The UAS Training Concept: A General Notion for UAS Training

The contribution that UASs make to the modern battlefield results from a synergy among the platforms themselves, those who operate the platforms, and those who incorporate the UASs into the battle. Combat power cannot expand unless all three work together. A platform flown

Table 3.1
UAS Tiers by Service

Group	Capability	Examples
I	Hand-launched, self-contained, portable systems employed for a small unit or base security.	RQ-11A/B Raven
II	Small to medium in size and usually support brigade and intelligence, surveillance, reconnaissance, and target acquisition requirements.	ScanEagle
III	Operate at medium altitudes with medium to long range and endurance.	RQ-7 Shadow
IV	Relatively large UASs that operate at medium to high altitudes and have extended range and endurance.	MQ-1 Predator
V	Large, high-altitude, long-endurance UAV platforms	RQ-4 Global Hawk

SOURCE: DoD, 2011, pp. D-2 and D-3

[5] The terms *supported unit* and the *supporting UAS* are basic constructs of MTTP, 2011, p. 9.

4469 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

by a skilled pilot does not add anything to the battle unless those on the ground who are engaged know how to exploit the information and other support the UAS provides. Similarly, if the pilot and payload operator cannot respond to the ground commander, the support they provide will not be what the commander needs. Only when all three work together will UASs be effective as a force multiplier. This can be achieved through training and practice that brings the platform, the operator, and the users together, starting at home station and progressing through ever-more-complicated exercises at the major training centers, such as the National Training Center (NTC) at Fort Irwin, California; the MCAGCC at Twentynine Palms, California; and the Joint Readiness Training Center at Fort Polk, Louisiana. Accordingly, how to achieve this synergy is the fundamental organizing concept for UAS training.

Let us be clear. The organizing concept developed here is not built around the training of a UAS pilot or payload operator per se. Their proficiency is certainly a necessary condition for UAS operations but is not, by itself, sufficient to enhance combat power. Enhanced combat power is achieved through the synergistic process that brings the platforms, the operators, and the users together. It starts at home station with small UASs and builds through the echelons of the ground forces as larger UASs are integrated into the combat operations of higher-echelon formations. Properly done, the maintenance or refinement of proficiency levels for UAS pilots and payload operators will be achieved incidental to the training that should take place with ground forces. But even before training can start, the services must decide how these systems will be used and how they will be incorporated into the force.

A Concept of Operations for UASs Is a Prerequisite for Training

As noted in the previous chapter, UASs are a classic disruptive technology. Integrating them into existing military operations is still a work in progress. This creates a problem for those charged with building training programs because, before training can start, the services must decide how these systems will be used and how they will be incorporated into the force. The services are still learning how best to use these new systems and the capabilities they provide. Each service is doing it differently.

Army

Initially, the UAS was thought of as just another platform for RSTA sensors, and the intelligence community was the proponent in the Army. In 2003, proponency for UASs transferred from Army Military Intelligence to the Army Aviation Branch. Since then, the UAS role in the Army has been changing from the relatively passive intelligence-gathering mission to the more active scout-reconnaissance and attack missions. One consequence of this transition is that UAS operators frequently team with manned aircrews to perform the scout-reconnaissance role. However, UAS operators and manned aircraft crews are currently separate communities and undergo separate programs of training.

At another level, the Army is experimenting with how to support the Raven, a small, hand-launched UAV. There is no dedicated military occupational specialty (MOS) for Raven operators. Being a Raven operator is an additional duty that requires additional training. Master Raven Training, a three-week train-the-trainer course, takes place both in the classroom and in the field. Students are taught how to maintain and operate the equipment and how to judge when and when not to fly. The plan calls for the trainer to return to home station and train squad-level personnel to operate the Raven.

4470 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Navy

The Navy has a different scheme for integrating the Fire Scout UAS and Broad Area Maritime Surveillance (BAMS) into the fleet. Typically, maintainers and pilots for Fire Scout have already gained technical training on manned helicopters. The Fire Scout–specific training is six weeks long and takes place at the Fire Scout Training Center at Naval Air Station Jacksonville, Florida (U.S. Army Maneuver Center of Excellence, undated).

The Navy's version of the Air Force's Global Hawk is the MQ-4C Triton, developed under the BAMS program. While the Navy continues to fly it to refine TTP for use in a maritime environment, the concept is for it to be integrated into active Navy maritime patrol units to complement the P-8 Poseidon, Boeing's 737–based multimission maritime aircraft, a traditional manned aircraft.

Air Force

The Air Force has yet another concept of operations that emphasizes remote split operations and reaches back to the Global Operations Center at Creech AFB, Nevada. Today, six operations centers in the continental United States (CONUS) support five launch-and-recover units in theater. Integration with tactical units is through tactical air control parties (TACPs) at the division, brigade, and battalion levels, and often at lower levels when supporting special operations forces (SOF). The TACPs coordinate directly with the Predator operations center via ultrahigh frequency radios on the aircraft or via satellite communications. As with other Air Force assets (and many air assets of other services), UAS assets are assigned to support ground commanders through the ATO. In the Air Force, the UAS pilots and payload operators are commissioned officers.

Marine Corps

The Marine Corps has dedicated UAV squadrons located at the MCAGCC at Twentynine Palms, California, and recently at Camp Pendleton, California. In the Marine Corps, enlisted Marines are responsible for almost every facet of the mission, from flying the aircraft and operating the payload camera to takeoffs and landings.

Summary

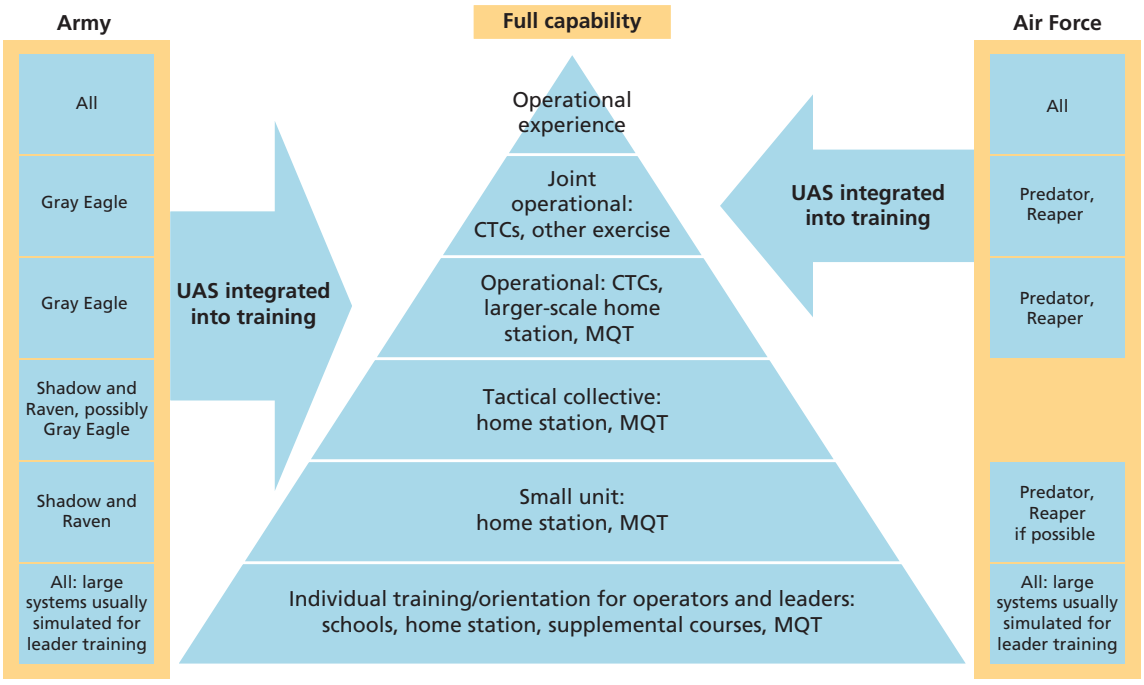
Even as the services are experimenting with the best way to use UASs and to integrate them into their forces, the overall purpose for UAS training should be clear. It is to increase combat power through the synergistic process that brings the platforms, the operators, *and the users* together. Putting these pieces together is the primary theme of the training framework we present.

Training Framework for Tactical UASs

The focus of the UAS training framework we offer is the enhancement of combat power, which starts with well-trained individuals who learn to work as a unit and ultimately leads to units that coordinate their efforts to produce military force. As we have seen, however, each service uses UASs differently.

Moreover, the great variety of UASs adds to this complexity. UASs are classified into tiers. Military planners designate the various individual aircraft elements in an overall usage plan using a tier system. The tiers do not refer to specific models of aircraft but rather to roles the

4471 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING



aircraft typically fill. Table 3.1 shows the UAS groups and their roles and offers the examples of systems assigned to them.

The following discussion of training frameworks refers primarily to tactical UASs and not such Tier V systems as Global Hawk and its naval variant, the BAMS-D Triton.

The Training Framework for Ground Combat: Army, Marine Corps, and Air Force

The pyramid shown in Figure 3.1 represents our idea of the training framework to enhance combat power for the Army and Marine Corps, integrating organic UASs and Air Force UASs, when available, in support of ground forces. It is a graphic representation of the synergy achieved through training and practice that brings the platform, the operator, and the users together, starting at home station and progressing to higher echelons and ever-more-complicated battle exercises. The services have committed to align their training with the agreed-to MTTP. As with any good framework, the UAS framework must have a strong base. The base of this framework, represented by the lowest level of the pyramid, includes the initial and individual skills training of those who operate, maintain, and use the systems. The higher levels of the pyramid roughly align with the echelons of ground forces from the platoon or squad level through the company level and moving up to battalions, then to brigades. Each level incorporates the C2 of subordinate units to create combat power that is more than the sum of its parts. A battalion is more than just a collection of companies, each of which is more than just a collection of platoons and squads. In creating this combat power, the battalion utilizes UASs that are not normally available to its subordinate companies. In this way, the battalion and its UASs are "combat multipliers." This increase of combat power is repeated as we move up the pyramid to higher echelons each supported by the UASs that are organic to that

Figure 3.1
UAS Training Framework for Army, Marine Corps/Air Force Joint Combat Operations

RAND *RR440-3.1*

4472 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

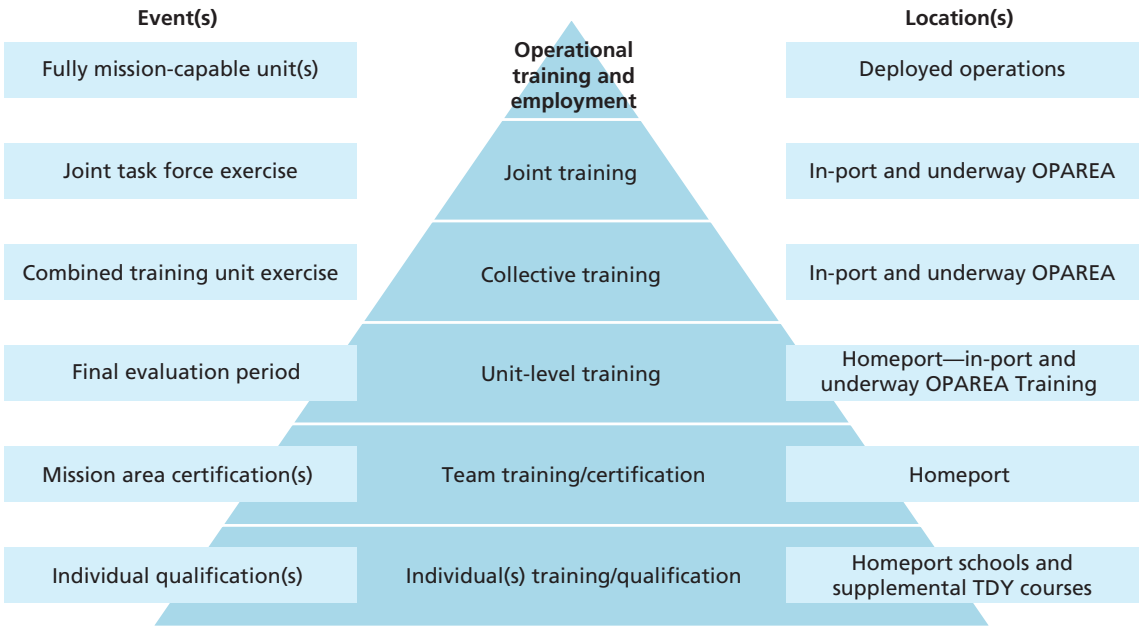
tier. The two different-sized arrows, coming in from the left for the Army and from the right for the Air Force, show the specific UASs and the echelons they support.

In our concept of the training framework for UASs, the ground force systems—those of the Army and Marine Corps—and Air Force systems are "stacked" along the sides and paired with the level of the pyramid they support. The entries at each level of the pyramid identify the type of training that needs to be accomplished and where that training takes place. For example, small-unit training, at the lowest level of the squad and platoon, incorporates the Raven UAV and is accomplished at home station. Company training, which generally entails C2 of four platoons, is also accomplished at home station. The individual platoons may each be using their own Ravens, and the company commander may have access to the information from a Shadow UAS.

This process is repeated at home station with companies being brought together under the C2 of the battalion commander and his staff. During a battalion exercise, the battalion commander will generally be able to task the Shadow UASs either individually or as part of the combat support from assigned Army aviation. In some cases, this may include information provided by the Gray Eagle UAS. In some instances—these have historically been very rare—available Air Force UASs, such as Reaper or Predator, may support home station battalion exercises.

Brigade-level training can be carried out at some home stations, but the maneuver combat training centers (CTCs) generally provide a better venue. All available Army UASs will support these training exercises, from the small Ravens to the larger and higher-flying Gray Eagle, when available. In addition, it is at this level and during these exercises that joint Army–Air Force support is usually integrated to include close air support (CAS) and support from Air Force UASs.

Not shown on the pyramid is the training needed to meet the certification requirements of UAS operators. Such requirements will normally be met incidental to their training with ground forces. For example, Shadow operators need to operate their equipment 4.5 hours per month to maintain their certification. It is expected that they will be spending more than that supporting ground units during home station training. Operators not actively engaged with the training of ground units can achieve the needed proficiency training using the same training equipment as during their initial skill training.



The Training Framework for Fleet Operations

A similar pyramid also represents our framework for Navy UAS training (Figure 3.2). It differs from the previous pyramid in that the Navy does not have a hierarchy of systems introduced at higher echelons of command. At the tactical level, the only UAS the Navy has is Fire Scout, which will be introduced into fleet operations following a similar path as discussed above. As with land forces and the systems that support them, combat proficiency is generated through the synergy of the platform, operators, and staffs that incorporate the UASs into the battle planning. Initial operator training is the base of the pyramid and takes place in the schoolhouse in the vicinity of the homeport. Operational training occurs under way in fleet operating areas. The Navy trains continuously, and the training continues through the operational use of UASs when the units are deployed.

UAS operators and maintainers require initial training to obtain the skills needed for operational effectiveness. As individuals become qualified as UAS operators and maintainers, they undergo team training to achieve mission area certification. For example, UAS operators

4473 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Figure 3.2
UAS Training Framework for Navy Tactical UAS

RAND *RR440-3.2*

may be linked to and integrated with an antisurface warfare mission team to support certification for the surface warfare mission area. For ships, unit-level training occurs both in port and under way and culminates in a final evaluation period. During that evaluation, the immediate superior in command evaluates the ship in all mission areas to determine that it is ready for advanced phase training. The final evaluation period comprises in-port and underway training events geared to assess the unit's ability to operate independently.

Collective training occurs after the final evaluation period, when the ship begins to operate with other units and staffs. During this time, the ship conducts operations with and becomes an integral part of a carrier strike group (CSG).[6] Collective training is a combination of in-port and underway training events and culminates in a combined training unit exercise evaluated at the fleet commander level. The Navy is in the process of developing its UAS tactics and procedures and plans to integrate UAS training into predeployment preparations.

Deployed naval ships and units must also operate in a joint environment. After completing a combined training unit exercise, a deploying CSG conducts a final exercise with elements of other services (e.g., Air Force aircraft) to demonstrate its ability to communicate and operate effectively in joint warfare. Joint training is conducted both in port and under way. An underway joint task force exercise is the culminating event, with Navy units operating with forces of the other services; on satisfactory completion, units are deemed ready to deploy. Units then continue the operational training and employment of their systems en route to their deployed operational areas.

[6] While we address surface units as being part of a CSG, surface units can also deploy independently, with other ships, or with an expeditionary strike group.

4474 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Navy units deployed to 5th Fleet do have experience with BAMS–Demonstrator (BAMS-D), the predecessor to the Triton, and a variant of the Air Force's Global Hawk. Despite being a demonstrator, BAMS-D was deployed to meet surveillance needs in the 5th Fleet. Navy strike groups operating in 5th Fleet were provided with imagery and data feeds from BAMS-D and used these data to build a common operational picture, which increased situational awareness. The BAMS-D was integrated into actual fleet operations and provided near-real-time updates for surface surveillance. Units learned to use BAMS-D "on the fly," by processing, exploiting, and disseminating imagery and sensor data; building the surface picture; and increasing the positive identification of surface contacts in the area of operations.

As UAS assets are fielded, they will be incorporated to a greater degree into predeployment training and increase opportunities to train and hone the tasking, collection, processing, exploitation, and dissemination of UAS sensor data.

Applying the Training Framework

The training framework presented here focuses on the synergy among three key elements: the platform itself, those who operate the platform, and those who incorporate UASs into the battle. The framework emphasizes using UASs to enhance warfighting proficiency. It provides a useful tool for organizing and evaluating training options and assessing the current state of training and plans for improvement. As discussed in the next chapter, we used the framework to assess the state of UAS training, as it existed in 2012.

4475 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

CHAPTER FOUR

Assessment of the State of UAS Training in 2012: Service and Interoperability Training and the Role for Simulators

For more than a decade, UAS training has concentrated on preparing UAS pilots and payload operators to support ongoing operations in Afghanistan and Iraq. This remained true in 2012 and 2013, and the services continue to evolve how best to use these systems and integrate them into ongoing operations. With the operations in Afghanistan winding down, the services must now integrate all facets of UAS training, including the infrastructure for training addressed in Appendix C, into a largely CONUS-based inventory of UASs that continues to grow, even as real-time operations continue for some systems.[1] Moreover, operational demands and technical innovations will continue to evolve and affect training and organizational requirements. As a result, UAS training and training support programs must be viewed as works in progress.

In assessing the current state of UAS training, using the UAS training framework discussed in the previous chapter, we view proficiency in flying UASs not as an end in itself but as only a means to an operational end: accomplishment of a military mission. As noted, this is achieved through the synergistic use of UASs with the forces they support, in ways similar to those in which the timely integration of intelligence or the delivery of fire support is accomplished in combat operations. This convergence requires full integration of UASs into the collective training of operational forces, attendant training and education for leaders and staffs, and the integration of lessons learned from previous and ongoing operations into education and training programs.

The preceding should by no means be construed to understate the need for training those directly involved in the operation of UAS—among them pilots, crews, support personnel, and those who maintain the aircraft and communications systems. Such training, both to develop and to maintain proficiency in the operation of UAS, is critical for the overall success of a UAS training strategy. But proficiency in these areas is not in itself sufficient. Full understanding of UAS integration, from the smallest to the largest systems at every echelon, as outlined in the previous chapter, is also necessary.

To be clear, members of the UAS community not only must understand how to operate their systems—a challenge largely being met successfully—but must also be familiar with the fundamentals of the operations they support and how their capabilities contribute to the successful accomplishment of the mission. Similarly, battle staffs must fully understand the many capabilities of UASs, how these capabilities supplement or complement other capabilities available to the joint force, and how best to integrate the capabilities into their operations.

[1] The Air Force UAS community believes high demand for its systems—Predator and Reaper—will persist, with requirements to support other kinds of demands increasing as demands for support of ground maneuver operations decrease.

4477 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

This chapter assesses the state of training for UASs across the ground, air, and sea forces. It discusses information, observations, and insights gained from a wide variety of sources but mainly through visits to a select number of service bases in 2012. During these visits, the RAND team talked with operators and support personnel; those who train operators and associated members of the team; those who train and observe the forces who employ UASs; staff elements concerned with the planning and resourcing of training, both for UAS operators and for the force more generally; and those concerned with the ongoing development of doctrine and concepts of operations for UASs, including their integration into operations. What follows is a compilation of the observations and insights from these individuals and our interpretation of the implications for the specification and resourcing of training strategies.

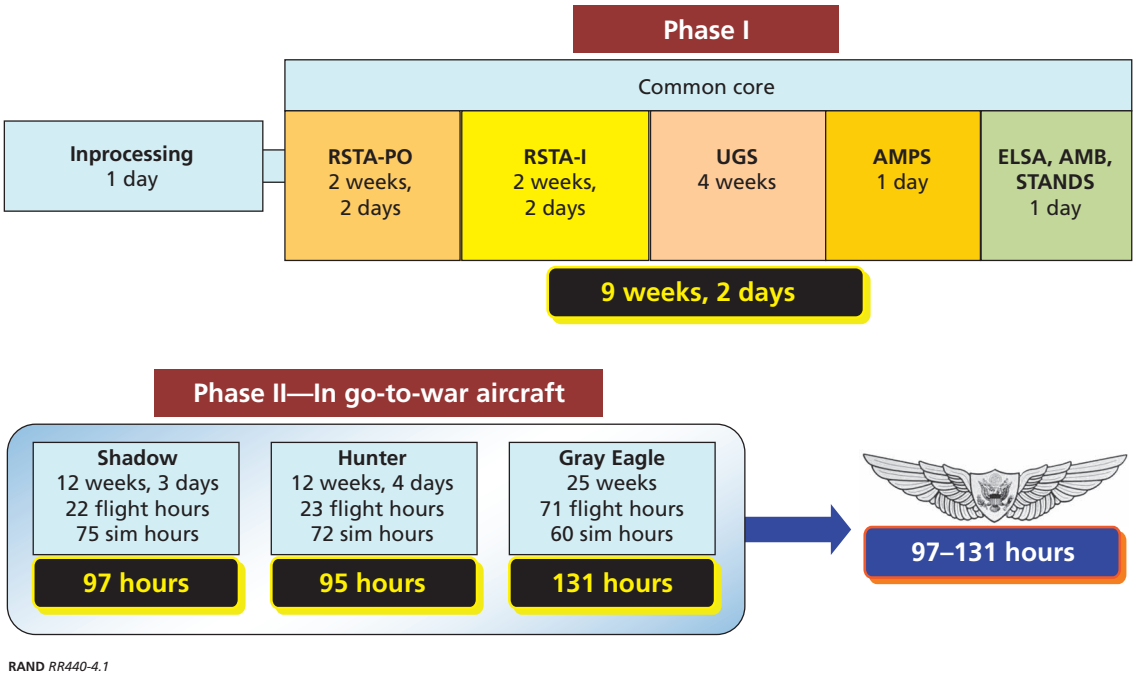
Ground Forces

Ground force operations of the Army and Marine Corps, even at low echelons, can be highly complex, and the complexity increases significantly at higher echelons. Commanders at higher echelons not only have to coordinate and use the information and capabilities subordinate units provide but also have to manage and integrate information and capabilities from a widening variety of other sources available to them. Adding the integration of UAS capabilities into the operational command further increases its complexity and thus the complexity of associated training management processes. Evidence from both training exercises and actual operations in combat theaters shows that, when properly managed, UASs provide significant new capabilities that commanders at every echelon can effectively employ. UASs truly have the potential to be force multipliers—but more so when employed by users fully competent in integrating their capabilities with those of the rest of the force and its supporting elements.

As shown in the training framework presented in Chapter Three, the proper integration of UASs to create combat capability starts with the training of UAS operators and support personnel and progresses through the integration of UAS operations with supported forces.

Training for Operators and Support Personnel

In general, the RAND team found that qualification training in the Army and Marine Corps for designated UAS-specific MOS is well established. In the Army, positions are filled by enlisted soldiers. The ranks of operators typically range from private first class to master sergeant (E-3 to E-8). The Marine Corps is organized much like the Air Force, with a UA commander who is a company grade, qualified aviator or aviation C2 officer on his or her second or third tour (O-3/O-4) and a mission payload operator (MPO) who is typically a corporal through master sergeant (E-3 to E-8).



Army Air Vehicle and Sensor Operators for Hunter, Gray Eagle, and Shadow UASs

Training for Army UAS operators—pilots and payload operators—is carried out in two phases: The first, at Fort Huachuca, consists of a common core course for all operators of UASs not launched by hand.[2] This phase lasts nine weeks and two days and has five sections. (See Figures 4.1 and 4.2.)

[2] The 2nd Battalion, 13th Aviation Regiment, which was previously called the Unmanned Aircraft Systems Training Battalion, conducts the training. See Appendix D for RAND's "military value analysis of training bases" assessment of training at Fort Huachuca, Arizona.

4478 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Figure 4.1
Army UAS Air Vehicle Operator and APO Training Pipeline

RAND *RR440-4.1*

After completing Phase I, the operators continue to Phase II. This section is unique for each airframe and consists of both simulation and flight hours. It typically takes 12.5 weeks for Shadow and Hunter classes to finish and 25 weeks for Gray Eagle classes. After completing Phase II, the UAS operators earn their wings.

Maintenance for Hunter, Gray Eagle, and Shadow UASs

The Army UAS maintainers take the MOS 15E Repairer course from the 2nd Battalion, 13th Aviation Regiment (see Figure 4.3). As shown in Figure 4.4, the course lasts 17 weeks, and a new class of up to 16 students starts every two weeks. After completion, 15E personnel are qualified to maintain the Shadow. Maintainers must take additional training to earn additional skill identifiers and thus qualify to maintain the Hunter and Gray Eagle. The additional training takes ten weeks for Hunter and 18 weeks for Gray Eagle.

Army Raven Operators

Without a dedicated MOS, the development and maintenance of Raven operators is a unit personnel and training management issue. Assignment as a Raven operator is an additional duty. In the past, this has meant that many units did not have the required Raven-qualified personnel to employ the systems properly. The Army is well aware of this problem and, short of creating a dedicated MOS, has recently initiated a program to deal with the Raven training problem. The Army Maneuver Center of Excellence at Fort Benning manages a certification course designed to qualify selected soldiers as small UAS (SUAS) master trainers capable of conducting initial qualification training (IQT) and certification of new operators at home stations throughout the Army. This train-the-trainer course focuses on how to teach and manage an aircrew training program at home base and how to assist small-unit commanders in evaluat-

ing academic and flight instruction and managing SUAS accident prevention.[3] It is envisioned that new master trainers returning to their home stations will be able to develop and maintain

[3] The 15-day course includes classroom and hands-on training, with instruction on reporting procedures, fundamentals of instruction, semiannual evaluations, and familiarization with Raven A and B and digital downlink systems. At the conclusion of the training program, graduates should have the ability to evaluate and certify operators. See U.S. Army Maneuver Center of Excellence, undated.

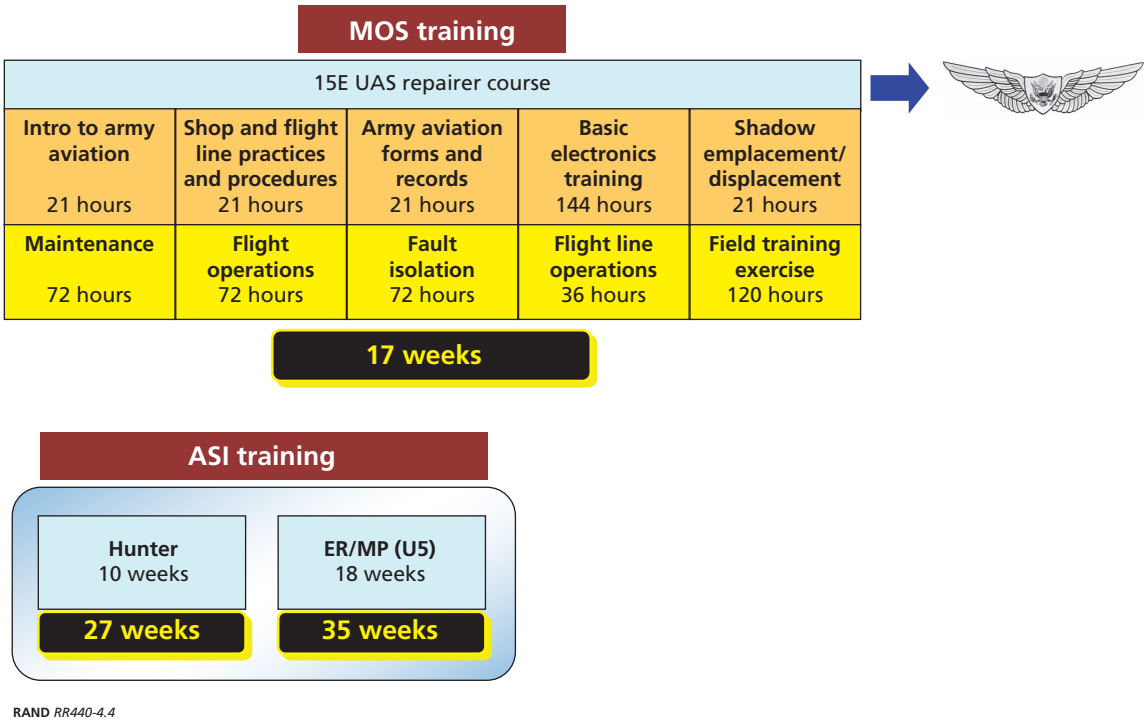
RAND *RR440-4.3*

a sufficient number of operators within their units and manage a tracking program to ensure that their units have the required number of certified Raven operators.

Marine Corps Unmanned Aircraft Commanders—Pilots



Training begins with the Unmanned Aircraft Commander course, which last two weeks and is taught by the U.S. Army at Fort Huachuca. Career-level training takes place at the squadron level. Marine Aviation Weapons and Tactics Squadron 1, at Marine Corps Air Station Yuma, Arizona, provides advanced training (the Weapons and Tactics Instructor course).

Air Vehicle Operators and Mission Payload Operators

Training for air vehicle operators (AVOs) and MPOs is accomplished jointly with the U.S. Army at Fort Huachuca. USMC operators take the nine-week common course and the 12-week Shadow course. Career-level training takes place at the squadron level. Marine Aviation Weapons and Tactics Squadron 1 provides advanced training.

Operational Training[4]

Larger UASs have dedicated MOS training, so operators and maintenance personnel arrive at home station having completed their IQT. To maintain their proficiency and certification, crews must log a minimum number of flying hours. The Army's Gray Eagle UAS has its own simulator capability built into the operating hardware. Currently, the Army's requirement is for 4.5 live flying hours per crew per month for the Shadow UAS. The Army has had difficulty maintaining sufficient numbers of Raven-qualified SUAS operators, in part because units do not always do well in tracking their qualified operators, maintaining their proficiency through hands-on work, and providing for their timely replacement when they move on. Discussions with Army trainers indicate that, despite the demands of deploying units and sustaining combat operations in Afghanistan, Army units are doing better at maintaining Shadow qualification. Nevertheless, not all units have been able to maintain high Shadow qualification rates: Some units arrive at the NTC with one-half or fewer of their operators qualified.

For these systems, the critical issue for the future will be securing enough flying time for UAS crews to train with ground forces. Marine Corps experience offers a good illustration of this issue. The Marine Corps has based Shadow squadrons at the MCAGCC, where there is adequate restricted airspace both to maintain crew proficiency and to fly in support of ground forces. However, both the ground trainers and squadron personnel the RAND team interviewed reported having to start what was essentially remedial training because the ground

[4] Joint Publication 1-02 defines *operational training* as "training that develops, maintains, or improves the operational readiness of individuals or units" (JP 1-02, 2013).

4482 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

forces were not adequately trained at home station to integrate UAS capabilities into their operations. These students generally could not progress to the level of proficiency desired.

The foregoing suggests the biggest challenge in developing and implementing a training strategy for UASs is gaining and maintaining proficiency on the part of end users—the leaders and staff members who will integrate UAS capabilities into their operations.[5] Ground units that undertake joint training at CTCs are often unprepared to use organic and nonorganic UASs effectively, and thus tend to develop battle plans that underutilize them.[6] Further, their intelligence and operations staffs sometimes find themselves at cross purposes over employment of UASs, an issue that could be better dealt with during home-station training.

Despite all this, discussions with operators, users, trainers, and training managers suggest that properly employed UASs consistently prove to be valuable combat multipliers. One example was an Army unit training at the NTC, which had successfully employed its UASs as part of a manned-unmanned team. In this instance, the UAS had acted as a scout and observer as manned attack helicopters delivered fires on selected targets, all in support of a ground maneuver unit. Another battalion well versed in the myriad tasks associated with employing Shadows—communication of commander's intent and concept, priority and time sensitivity of information requirements, targeting priorities, use of the communications relay package, to list just a few—was far more successful in employing the Shadows supporting it than another unit was. In the latter unit, the UAS platoon was simply given "areas to look at," without specific guidance on what to look for, e.g., named areas of interest and targeted areas of interest. Interviewees told the RAND team that many UAS operators do not get enough opportunity to interact with either crews of manned aircraft or the elements of ground units—commanders and operations and intelligence sections—that they will support.

The latter problem, ground units' lack of experience in employing UASs, is all too common. It is also true for the USMC, whose units face considerable limitations on using UASs at their home stations or local training events.[7] Marine ground force units are thus typically not well versed in employment of UASs when they arrive at Twentynine Palms. Although they learn while there, many are still not fully capable when they deploy.[8]

Improvements in Facilities and Basing for UASs Will Improve Training Integration

To date, the Army has had reasonable opportunity to train at home station, and current programs to increase UAS facilities will appreciably add to this. Table 4.1 summarizes responses the U.S. Army Training and Doctrine Command (TRADOC) received from active, National Guard, and reserve bases in November 2012 concerning the availability of restricted airspace and resulting limitations on UAS operations stemming from lack of availability. The responses

---

[5] We refer to anyone who could benefit from the information a UAS provides as an *end user*. The MTTP calls end users *supported units*.

[6] *Organic* assets are ones owned by a unit, and *nonorganic* assets are ones that the commander of a unit does not own and thus does not have full control over.

[7] Recall that the Marines' Shadow squadrons are based at Twentynine Palms when not deployed.

[8] This brings up the question of whether we should expect units to continue learning sound tactics and procedures while they are deployed. They should, of course. The issue is how much; officials we have consulted have given us the sense that many units are still on the steep part of the learning curve when they leave the MCGACC. These units would be more operationally effective sooner in their deployments if they could be better trained to integrate UAS capabilities before they deploy.

4483 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

indicate that, in many cases, relatively minor military construction projects are all that is necessary to expand training opportunities at home stations. In most locations, additional beddown facilities will allow better use of existing restricted airspace to facilitate live training. In a few cases, however, the proximity of training areas to the Federal Aviation Administration (FAA)–controlled National Airspace System (NAS) remains a problem. The summary in Table 4.1 provides a snapshot of the kinds of issues that have already been raised and will have to be revisited at some point because of the ongoing pressure to reduce defense budgets.

Table 4.1
Select Summary of Army UAS Installation Survey as of November 21, 2012

Base/Commands	Answer To Question E: Does Available Restricted Airspace Affect/Limit UAS Operations at Your Installation?	Answer To Question J: What Solutions Would You Recommend for Unsolved Issues?	Shadow Strips Planned for FY 2013
Alaska (Forts Wainwright and Richardson)	No.	We have been able to accommodate all down range requests. However, the hangars are nonstandard and need to be evaluated for suitability as the Shadow and Gray Eagle platforms evolve.	
Fort A. P. Hill	During landings the tactical approach landing system orbit is outside the restricted airspace.		Yes
Fort Bliss	Our special use airspace is bisected by a major highway which requires a COA.	Yes, a Shadow Strip in the SUA.	Yes
Fort Bragg	Yes.	Yes. Primarily commercial power and hardened maintenance facilities. Temporary solutions are power generation equipment and tentage.	Yes
Fort Carson	Yes, limited by the volume of manned/unmanned platforms operating within the airspace.	Yes, requests for designated UAS facilities and airstrip for launches and recovery. Funding established to build a multiple platoon facility for UAS units.	Yes
Fort Drum	No.	No. We have no unresolved UAS issues.	Yes
Fort Hood	Not currently.		
Fort Knox	No.	Yes; the construction of a tactical UAS field support structure (build it).	
Hawaii	Yes, we have requested to use the Kahuku and East Ranges for flights but due to FAA restrictions, we cannot fly UAS/SUAS platforms in these airspaces.	No. We need more airspace to train in. Our current location is becoming less and less amicable to flight conditions due to public demands on land. In 2010, plans were drawn up to provide for a permanent UAS facility at Wheeler Airfield, but they were cancelled due to program funding.	

4484 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Table 4.1—Continued

Base/Commands	Answer To Question E: Does Available Restricted Airspace Affect/Limit UAS Operations at Your Installation?	Answer To Question J: What Solutions Would You Recommend for Unsolved Issues?	Shadow Strips Planned for FY 2013
Fort Lewis (Joint Base Lewis-McChord [JBLM])	1. Yakima Training Center (YTC): No not an issue. 2. JBLM: Yes, both the limited restricted airspace and the large number of installation units requiring restricted airspace, challenge UAS/SUAS operations.	1. YTC: Shadow Training Facility 2. JBLM: Construction of a second Shadow landing strip. 3. JBLM: Construction of any type of permanent, securable facility alongside the existing Shadow landing strip (location is outside JBLM's guarded area). 4. JBLM: Shadow Training Facility or TEMF.	
Fort Riley	Not currently. (See response to Q h & i.)	Nothing to comment on.	Yes
Fort Stewart	Not significantly. However, reductions in air traffic control manning are a concern. There are currently no significant restricted airspace challenges negatively affecting UAS operations.	Funding, we have a plan and the requisite site approvals, we just need funding support. We need the funding ($701,000) now for our third Shadow platoon hangar; we have the design ready to go and at contracting.	
USAREUR	Yes. 173rd Shadow out of Italy is currently based in Bamberg due to no restricted airspace to fly in Italy. Currently fly in restricted airspace in Grafenwoehr/Vilseck Training Areas.		
Camp Atterbury	No, both UAS facilities are within restricted airspace.		
Fort Chaffee	No restricted airspace limitations to TUAS flight operations.		Yes
Orchard Range	Yes, UAS operations are limited to using R-3203.	Fixed support facilities UAS operations. Facilities will be in Range Complex Management Plan.	
Fort Pickett	No, we have one of the largest SUAs in the Midatlantic.		
Camp Ripley	No, the restricted airspace at Camp Ripley (R-4301) provides enough area to conduct training for the current systems.	Yes. The current tactical strip will be removed for the construction of a MPTR. UAS commanders have requested a tactical strip for replacement that includes hard-stand buildings and electrical power. The Combat Readiness Training Center currently has a location selected that has power in close proximity to the existing tactical strip. Camp Ripley is one of the sites to receive $730,000 for construction of a UAS strip in the down-range area in FY 2013.	Yes
Camp Roberts	No.	Funding.	Yes

4485 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Table 4.1—Continued

Base/Commands	Answer To Question E: Does Available Restricted Airspace Affect/Limit UAS Operations at Your Installation?	Answer To Question J: What Solutions Would You Recommend for Unsolved Issues?	Shadow Strips Planned for FY 2013
Fort Dix	Yes.	We have accommodated all downrange requests. However, the size restriction of the UAS in R-5001 limits operation of large UAS operations.	
Fort Hunter-Liggett	No, we use R-2513 airspace.	None.	
Fort McCoy	Yes, Current coutilization of Young Air Assault Ship, a 6,250-ft. C-17/C-130 landing strip in R-6901 B. The UAS operations at this landing strip affect Sparta/ Fort McCoy airport operations.	Yes. Hangers for Shadows and permanent facilities with commercial power, and asphalt. Standard design and funding required.	
Fort Campbell	Fort Campbell currently has two approved sites for Shadow Flight operation; both are located among numerous field artillery firing points, which requires de-confliction during launches and landings because the firing points have to check fire. As a result, UAS flight training is significantly reduced. However, an additional UAS strip is being constructed to alleviate this problem.	Yes. Permanent facilities with commercial power and utilities.	

SOURCE: Installation UAS survey responses from TRADOC Capability Manager—Live, as of November 21, 2012.

Key Areas of Concern

As the war in Afghanistan draws to a close, the services must pay close attention not only to the training of UAS crews and support personnel but also to the routine exercise of these systems as part of combined arms training at home station and at the CTCs. This will require attention to a number of issues.

Beddown and Related Support Facilities

To facilitate the efforts described above, DoD should support current and future programs to develop ranges and beddown and support facilities similar to those in the Army's current programs. The Army has been implementing a robust program to establish Shadow beddown facilities—runways, shelters, and attendant support structures—on many of its installations, both active and National Guard. This will enable more opportunities both for UAS operators and for end users.

Airspace Considerations

As the responses reported in Table 4.1 suggest, the unique limitations of UASs pertaining to operations in the NAS can make integration into home station training difficult. Currently, UASs can operate only in restricted military airspace or, in the NAS, with certificates of authorization (COAs) from the FAA. In some cases, it should be possible to increase UAS training with ground forces (and with collocated manned aircraft units) without impinging in any significant way on the NAS. Although this will certainly require better coordination of restricted airspace at individual installations, better availability of restricted airspace will make better

4486 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

access to the NAS less of a key element in supporting training strategies, at least as they pertain to home-station or local training of ground forces. However, less-cumbersome procedures for NAS access will, among other things, facilitate opportunities for units to employ larger UASs, such as Gray Eagle, Predator, and Reaper, in home-station training events.[9]

Air Force

The Army and the Air Force have significantly different concepts for employment of UASs. The Air Force uses a remote split operations concept to employ its UASs. Under this approach, the Air Force flies UASs from home station using satellite or other relay links. It maintains only small deployed footprints at consolidated operating locations to launch, recover, and maintain the aircraft.[10] This approach enables the deployment of the vast majority of its systems, yet the majority of the personnel who operate Air Force UASs do so from home station and require no reconstitution following deployments. By using remote split operations, 85 percent of the Air Force's UASs would be forward deployed for combat operations. The remaining 15 percent would support training at each operational base. The Air Force employment concept, however, does not facilitate integrated operations with Army tactical-level units during training at Army home stations. Once deployed, Army brigades, battalions, and SOF must learn to work with Air Force TACPs to coordinate UAS operations.

Training for Pilots, Operators, and Support Personnel

The Air Force uses a crew of one pilot and one sensor operator to man each UAS mission.[11] The pilots are officers and are either rated pilots who graduated from undergraduate pilot training or UAS-only pilots who graduated from a new program called undergraduate remotely piloted aircraft training.[12] UAS-only pilots have the 18X Air Force Specialty Code (AFSC) and will be discussed in more detail later. Following the structure of the training pipelines for other platforms, the training is broken into three phases: IQT, mission qualification training (MQT), and crew mission ready training. Air Education and Training Command conducts IQT and MQT, with the latter taking place in a formal training unit (FTU).

[9] In some cases, basing for the larger systems, especially Gray Eagle, will be contiguous with the training areas in which they are needed; Fort Hood, Texas, is an example. But this will not always be possible. The larger systems require longer and better runways and larger and more-sophisticated beddown and support facilities. It may be more cost-effective to move these UASs to support training where they are needed, rather than establishing beddown facilities in a large number of additional locations.

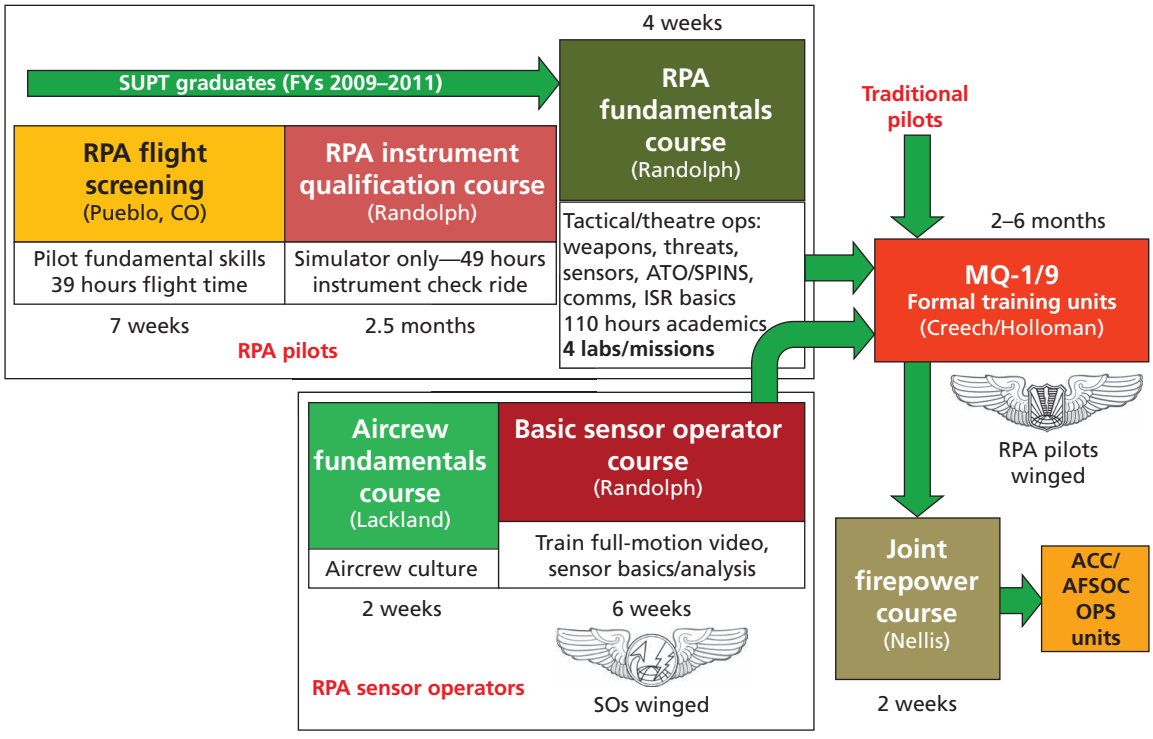
[10] The 432nd Wing at Creech AFB operates MQ-1 Predators and MQ-9 Reapers from seven forward bases overseas. Maintainers at forward bases serve four-month rotations in theater.

[11] Many more people are involved in RPA operations, including the mission intelligence commander. Also, there is a weapon school course for advanced training of RPA operations. For this research, we were primarily interested in the initial training of pilots and sensor operators.

[12] Some Air Force navigators who had commercial instrument qualifications have been allowed to train as pilots for the RQ-4. This avenue for sourcing RQ-4 pilots closed in spring 2011.

4487 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Pilots



Reaper and Predator

In response to the need to reach and sustain the manpower to fulfill Reaper and Predator requirements, the Air Force initiated a new program to produce RPA pilots.[13] Currently, Reaper training takes place at Hancock Field Air National Guard Base in Syracuse, and Predator training takes place at Holloman AFB. New RPA pilots have attained the foundational skills to conduct RPA missions and are qualified to operate in the NAS or International Civilian Aviation Organization airspace. Figure 4.5 outlines the training pipeline. Figure 4.6 shows the UASs.

Global Hawk

Currently, most Global Hawk pilots are traditional Air Force pilots who volunteered for a tour in the Global Hawk (see Figure 4.7), a majority of whom are qualified to fly multiengine transport aircraft. Prior to 2011, navigators who also had commercial pilot licenses and had completed commercial instrument qualifications were allowed to become Global Hawk pilots; however, the Air Force has not decided whether to retain navigators who are currently Global Hawk pilots in the community or return them to navigator duties. The third source of Global Hawk pilots is the 18X career field, UAS-only pilots who have graduated from undergraduate remotely piloted aircraft training. After finishing the three preparatory courses, candidate Global Hawk pilots head to the RQ-4 FTU, the 1st Reconnaissance Squadron at Beale AFB.

Figure 4.5
Air Force UAS Pilot and Sensor Operator Pipeline

RAND *RR440-4.5*

[13] The Air Force uses the term *RPA* to refer to unmanned aircraft systems. The accepted joint terminology is *UAS*.

Figure 4.7
Global Hawk UAS

SOURCE: DoD.
RAND *RR440-4.7*

Sensor Operators

Reaper and Predator

Enlisted sensor operators for Reaper and Predator are either trained into a new career field or cross-trained from another AFSC (1U00X). After graduating from the Air Force's basic training or being reclassified, they attend a two-week course at Lackland AFB, Texas, with other aircrew AFSCs. Then they go to Randolph AFB, Texas, for a six-week basic sensor operator course. After completion, they go to the appropriate FTU for the system they will be flying.

Global Hawk

Sensor operators for the Global Hawk are trained differently from those for other UASs. Sensor operators for the Global Hawk come from the intelligence imagery analyst career field (1N1XXs). They receive MQT at Beale AFB, where they learn to use the Global Hawk system. After one tour as sensor operators (approximately three years), they move on to other imagery analyst assignments; therefore, it is difficult to maintain expert sensor operators for the Global Hawk.

Maintenance

Training for those who maintain Air Force UASs takes place at three locations.[14] The fundamentals are taught at the maintenance schoolhouse at Sheppard AFB, Texas. Initial skills training and advanced skills training take place at the unit.

[14] Contractors provide certain UAS maintenance, for example, depot-level maintenance.

4490 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Operational Training

Given the emphasis on current operations and the Air Force's remote split operations concept for employing UASs, few opportunities exist to support ground troops either during home-station or CTC training. In general, with a few limited exceptions, Air Force UAS crews do not train in exercises or other training events in CONUS and do not support training in CONUS of Army or Marine Corps units at either their home stations or at the CTCs. Air Force UAS crews do conduct operational missions in theater, and these missions frequently are the chief or even the only way deployed Army and Marine Corps units get an opportunity to work directly with Air Force UAS crews. Thus, most elements of the UAS force in theater often have no experience working together before they have to do so in combat operations.

The result of not working with ground troops either at home station or the CTC is that ground units generally do not integrate Air Force UAS capabilities into their planning. RAND's conversations with the training community, including trainers at the NTC, as well as what officials told the GAO, confirmed that the

> effective integration of UAS in training exercises, like the integration of other types of joint air assets, depends on the priority that ground units place on developing training objectives that require the participation of joint air assets and their ability to plan for the use of these assets in the exercise. … [As a result], Army combat brigades often focus UAS training objectives during exercises on integrating their Shadow UAS and do not emphasize planning for and employing Air Force UAS.[15]

---

[15] Independent RAND team visits also confirmed what the Air Force told the GAO, that

> unmanned aircraft are deployed to support overseas operations except for those that are supporting the initial training of UAS personnel or the testing of aircraft." These officials [from the 432 Wing] stated that in the event that additional aircraft were made available, the wing's personnel levels are insufficient to support additional training events because the unit does not have adequate personnel to support projected operational commitments and greater numbers of training exercises. Second, Army and Air Force officials told us that when Air Force UASs are at the training center, these aircraft are not always available to support ground unit training because a considerable portion of the UAS flight time is dedicated to accomplishing Air Force crewmember training tasks. Officials told us that the Army and Air Force have reached an informal agreement to allot about half of the time that an Air Force UAS is flying at the training center to support Army ground unit training objectives and the other half to accomplish Air Force training tasks. Air Force officials pointed out that although they try to align their crewmember training syllabi with ground unit training objectives at the National Training Center, training new personnel to operate these aircraft is their priority. Third, UASs may not be available during certain hours to support ground unit training, which during exercises goes on 24 hours a day. For example, Predator UASs from the California Air National Guard are available to support ground units only during daylight hours. To travel to the training center, these aircraft must pass through segments of national airspace that are not restricted for DOD's use and therefore must rely on a ground-based observer or on chase aircraft to follow them to and from the training center. Because of this reliance on ground or airborne observers, flights to and from the training center must be accomplished during daylight hours and are necessarily more expensive as well.
>
> As a result of the limited number of unmanned Air Force assets that are available to support ground unit training at the National Training Center and the Joint Readiness Training Center, Army ground units conducting training exercises have frequently relied on manned aircraft to replicate the capabilities of the Air Force's Predator and Reaper UAS. Officials told us that the use of manned aircraft in this role permits ground units to practice the process to request and integrate the capabilities provided by Air Force UASs in joint operations. However, this practice is not optimal, as the manned aircraft do not replicate all of the capabilities of the Predator and Reaper aircraft, such as longer dwell times.

GAO, 2010a, p. 26.

4491 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Key Areas of Concern

We note above that, as the war in Afghanistan draws to a close, the services must pay close attention not only to the training of UAS crews and support personnel but also to routinely including these systems in combined arms training at home station and at the CTCs. This will require attention to a number of issues.

Beddown and Related Support Facilities

Discussions with officers of the 432d Wing suggest an Air Force future much like the past: flying in support of COCOM requirements worldwide. If this comes about, there will continue to be limited opportunities for the Air Force to support Army or Marine Corps training at the home station or CTCs. Alternatively, if providing such training becomes a priority, the Air Force's current basing and beddown posture will become a problem.

Airspace Considerations

The unique limitations of UASs pertaining to operations in the NAS make integration into home-station training difficult. Currently, UASs can operate only in restricted military airspace or, in the NAS, with COAs from the FAA. These COAs can often be prohibitive to participating in joint training. For example, the MQ-1 FTU from March ARB tried to participate in training with the Marines at Twentynine Palms. Unfortunately, the COA requires a manned chase plane and, given the geography, the contracted chase plane cannot fly the shortest route. The only option is to fly through the restricted airspace between Fort Irwin and Twentynine Palms, which is prohibitively long because the COA permits operations only during daylight hours. These limitations restrict where UASs can be used because an installation must have access to a significant amount of restricted airspace. Other limitations include the basing expense of sprinkling UASs across the country to embed with Army or Marine units at home station.

Several different possibilities could be considered to help increase joint training opportunities. The Air Force could consider the location of Army hubs when choosing where to base its UAS fleet. A location that is near Army maneuver elements might make airspace access less of a restriction or at least make COAs more practical. Proximity might provide more opportunities for training UAS integration throughout the entire mission planning process.

Alternatively, the Air Force could permanently leave a small number of UASs at a training location and remotely operate these from Holloman AFB, Creech AFB, or other locations. These systems are designed to employ remote split operations, in which the crew operating the platform need not be colocated with the platform. The various Air Force units could get flying time by cycling through these dedicated aircraft. This option would provide Air Force crews—including launch and recovery crews—practice integrating with ground forces and would simultaneously support the ground forces' need for integrated training. This plan would also reduce the issue of airspace access because the aircraft would be located within the restricted airspace in which they would be used or at an auxiliary airfield close enough that a COA would be practical.

A promising development that enhances UAS training is the advancement of ground-based sense-and-avoid (GBSAA) and airborne sense-and-avoid (ABSAA) technologies. These may open up regions of civil airspace for properly equipped UASs to operate safely in accordance with the FAA's mandate to "do no harm" without requiring FAA issuance of COAs. In particular, GBSAA has recently completed a series of successful demonstrations, and the

4492 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Army is planning to GBSAA equip a number of its UAS training bases to extend their current military airspace with adjoining civil airspace to increase UAS training capacity by 2015. The Army is the lead for the development of GBSAA, but GBSAA has been designed for the use of all the services. Each service, like the Army, would use one of its existing ground based radars in implementing GBSAA. ABSAA's implementation uses UAS-borne sensors and electronics, including those not currently on UASs. Current development of all-weather ABSAA that could operate without FAA COAs is restricted to Global Hawk, with plans to scale down to Reaper. ABSAA availability is not known at this time but will be some years after GBSAA becomes available.

Navy

Relative to the Air Force and Army, the Navy has had limited experience with UASs. To date, Navy ships have employed the Scan Eagle, a non–program of record UAS, fielded through a rapid-acquisition program (see Chapter Two). Scan Eagles are flown from frigates. The Navy has also operated BAMS-D,[16] which is scheduled to be replaced by the MQ-4C, Triton.[17] The Navy is acquiring the Fire Scout (MQ-8B). While we limited most of our study effort to the period through FY 2012, the Navy's most recent experience is the best example of the evolution of UASs and their implications for operational capabilities. In early May 2013, the Navy launched an X-47B experimental drone from the nuclear powered aircraft carrier USS *George H.W. Bush* as it operated off the coast of Virginia (Vergakis, 2013). This launch represented the latest step in introducing a disruptive technology into the operating forces and helped mark a paradigm shift in warfare because this particular UAS is capable of autonomous flight.

The Navy's approaches to integrating UASs and to training and developing UAS operators differ significantly from those of the Army and Air Force. Generally, Navy UASs are being incorporated into existing fleet aviation units and organizations, and the personnel who will operate them are, to a large extent, the same personnel who will operate traditional aircraft assigned to these organizations. In this way, the Navy is addressing several problems often seen when disruptive technologies are introduced. The Navy approach has emphasized the complementarity of the systems, rather than pitting the new technology and its proponents against the old technology and its proponents. In addition, the Navy will reduce cost by capitalizing

[16] While the Air Force has conducted Global Hawk UAS operations since 2001, the Navy has just recently pursued using the system. The Navy purchased Global Hawk airframes from the Air Force and is using them to test operational concepts and technologies. The aim for the Global Hawk maritime demonstration program, BAMS-D, is to better understand maritime surveillance with UASs that fly at high altitude. The goal is to improve the fleet's operational understanding of the battlespace, and the Navy deployed BAMS-D in 2009.

[17] The Navy's BAMS UAS (MQ-4C), now called Triton, is a persistent maritime intelligence, surveillance, and reconnaissance system. As a persistent airborne asset, Triton's sensors will support increased situational awareness for naval forces. The imagery and data provided by the airframe's sensors will be directly available within federated networks, allowing Navy, joint, allied, and coalition exploitation centers to use MQ-4C UAS data.

While the Navy is currently operating only BAMS-D (in FY 2012), it plans to purchase a total of 68 Triton MQ-4C UAS airframes from FY 2014 through FY 2026. This acquisition plan will increase deployment of BAMS to operational commanders throughout the world. The current concept of operations includes plans for the Navy to operate Triton UASs in five separate geographic locations. These operations would provide continuous maritime surveillance, with persistent ISR support 24 hours a day, seven days a week, out to ranges of 2,000 nautical miles from the deployed location. (Derived from Department of the Navy, 2010.)

4493 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

on investments already made in personnel aviation training. For example, the Fire Scout UAS will be embedded in Navy H-60 squadrons.[18] This enables taking advantage of H-60 pilots' training and experience, because they will also pilot the Fire Scout. The flying skills of the H-60 pilot are utilized for both airframes and minimize the potentially disruptive effects of this new technology. Similarly, Triton, the follow-on to BAMS-D, is intended to complement Navy P-3/8 aircraft with its long loitering capability and sensors. The Navy plans to have P-3/8 officers both be in tactical command of the UAS and pilot the Triton UAS. These officers will first serve and qualify in the P-3/8 aircraft, rotate to a UAS training unit, then assume duties in a UAS squadron. The Triton UAS capabilities complement the capabilities of the P-8 aircraft. The training construct the Navy is pursuing will capitalize, complement, and exploit the capabilities of both aircraft and the personnel assigned to them.

Training for Operators and Support Personnel

Scan Eagle

Qualification training for personnel directly associated with UAS operations is not yet well established for the Navy. Currently, contractors operate the Scan Eagle UAS. (See Figure 4.8.)

Fire Scout

The Navy will have two approaches for Fire Scout operator training—one for littoral combat ship (LCS) employment and another for SOF support. The majority of Fire Scouts will be flown from the LCS. (See Figure 4.8.)

Littoral Combat Ship Employment

The aviation detachment that will deploy with the LCS will consist of one H-60R helicopter and two Fire Scouts and will have 23 assigned personnel. The training these personnel will need is similar to that for deploying with H-60 detachments on guided missile destroyers today (normally, two H-60 helicopters deploy with a guided missile destroyer). In the future, ships will deploy with a mix of H-60s, and Fire Scout and aviation detachment personnel will fly both aircraft depending on mission requirements.

The skills needed to operate and maintain the Fire Scout are complementary to those needed for the H-60. The operators and maintainers of Fire Scout will be the same as for the H-60, with some additional training on the Fire Scout. An H-60 fleet replacement squadron's (FRS's) Fire Scout fleet introduction team will provide this training to the AVOs and MPOs en route. The AVO course for H-60 pilots lasts five weeks. This initial and all sustainment training for the Fire Scout will be conducted via simulator.

Fire Scout Support for Special Operations Forces

The Navy is establishing dedicated units to support SOF, rather than integrating Fire Scout into existing units. The first of these units, Unmanned Helicopter Reconnaissance Squadron One, will be both a training and an operational squadron. The Navy's plan is to organize each such squadron to have nine detachments, each consisting of three Fire Scout airframes, seven to eight AVOs, eight MPOs, and 16 maintenance and support personnel. The Fire Scouts that will be flown off LCSs will be piloted by commissioned officers. The Fire Scouts supporting

[18] The Fire Scout will greatly contribute to increased mission readiness and response by conducting persistent ISR operations immediately around seaborne task forces, as well as over the horizon. The persistence, range, sensors, and data sharing of UASs extend the ISR reach of Navy ships and increase situational awareness.

RAND *RR440-4.8*

4495 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

SOF units will be piloted by enlisted AVOs. Initially, these AVOs will be air warfare operators who have completed tours as MPOs with an LCS Fire Scout.

Fire Scout Maintainers

The Fire Scout maintainers consist of four Navy specialties. Enlisted aviation machinist mates and aviation structural mechanics will take the mechanical course for LCS Fire Scout. Enlisted aviation electronics technicians and aviation electrician's mates will take an electronic technical course for LCS Fire Scout. The maintenance and support skills needed for the Fire Scout are complementary skills for Navy enlisted technicians.

Triton

Operator Training

The MQ-4C Triton UAS is composed of several systems: the airframe; a suite of mission payloads; communications systems; a mission control system (MCS) used for mission planning, control, and execution; and a support system. The Triton UAS will be deployed as an adjunct system to P-3/8 squadrons. The MCS will be based at a main operating base in CONUS, and BAMS maintenance and launch and recovery operations will take place at a forward location.

The Triton watch organization will consist of a mission commander (P-8 naval flight officer),[19] one AVO (officer, P-8 pilot), and two mission payload (enlisted) air warfare operators. Training plans for the Triton watch organization are being developed, and the initial operating capability of Triton will be in FY 2016. The Navy plans to use P-3/8 pilots as tactical coordinators and AVOs on the Triton. Future aviators will first go through flight school, earn wings on the P-3/8 aircraft, then perform an initial operational tour on the P-3/8.[20] After that, aviators will rotate to the FRS for training on Triton before reporting to their squadrons. Designated FRS for BAMS is Patrol Squadron 30 (VP-30), located at Naval Air Station Jacksonville, Florida. FRS training provides initial and refresher qualification training for personnel who will be assigned to Triton units.

Maintenance personnel and the pilot who launches and recovers the airframe are located at the forward operating base. The Navy plans to rotate personnel through the forward base every several months.

A simulation training capability will be built into the MCS. Initial Navy manning plans indicate that there will be eight to ten crews per squadron. The crews will be flying real missions that will sustain their proficiency. Triton UASs are flown via point and click; there is no stick and rudder. VP-30 is developing the tailored Naval Air Training and Operating Procedures Standardization requirements for the Triton; the final training and readiness manual for Triton is due in 2013.

Maintenance Training

The Triton airframe, engines, and associated equipment are different from the P-3/8; one is a UAS and the other a manned aircraft. Separate training will thus be necessary. When the

[19] The mission control officer is a naval flight officer who is responsible for the mission planning and the overall tactical employment of the airframe. The AVO is a naval aviator, responsible for flight planning and safety of flight, and is the pilot in command of the airframe. The MPOs are enlisted air warfare operators, responsible for the operation and employment of the sensors and the detection and analysis of targets.

[20] The notional pilot training track for P-3/8 pilots is (1) attend and graduate from flight school, (2) attend FRS for P-8 training, and (3) conduct an operational P-8 squadron tour.

4496 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Triton UAS is introduced into the fleet, the Chief of Naval Air Technical Training will stand up a technical school to train enlisted personnel to perform Triton maintenance.

Operational Training

BAMS/Triton

The P-8A's missions overlap with those of Triton. The missions the two have in common include maintaining the maritime common operational picture and the classification, identification, detection, and tracking of surface units. The P-8A, however, has missions that the Triton does not perform (e.g., antisubmarine warfare) and vice versa. However, the increased utilization and cross training of P-8A and Triton crews over time can and is expected to increase understanding and employment of these systems in support of the warfighter.

While the Navy was operating only BAMS-D in FY 2012,[21] the Navy has plans to purchase a total of 68 Triton MQ-4Cs UAS airframes from FY 2014 through FY 2026. This acquisition plan will increase deployment of Triton UAS to operational commanders throughout the world. The current concept of operations includes plans for the Navy to operate Triton UAS in five geographic locations. These operations would provide continuous maritime surveillance, with persistent ISR support 24 hours a day, seven days a week, out to ranges of 2,000 nautical miles from the deployed location (Department of the Navy, 2010). The LCS does not have the Navy Continuous Training Environment (NCTE) synthetic training capability, and Fire Scouts assigned to the LCS will have no capability to train in the NCTE. Integrated training plans for Fire Scout are being developed.

Integrated Training

Triton's MCS will be configured so that it can participate in fleet training exercises synthetically via NCTE. Fleet synthetic training events for BAMS-D and Triton are being developed.

Key Areas of Concern

Airspace Considerations

Airspace planning is a critical requirement when conducting UAS operations but is less of a constraint for UASs in naval operations. The FAA controls the airspace up to the 12-mile limit from land. Navy surface ships with Scan Eagle and Fire Scout can embark the UASs, travel 12 nautical miles out to sea to a naval operating area, then conduct UAS training.

BAMS-D and Triton use special use airspace and fly at altitudes higher than commercial airlines do. They file instrument flight rules flight plans. However, BAMS-D and Triton do not incorporate sense-and-avoid technology, and conflicts can exist with visual flight rules aircraft in the airspace. Airspace issues exist at some Navy training installations as well. For example, along the North Carolina coast, the expeditionary readiness group must work with the FAA to route commercial aircraft around the established restricted operating zone units.

[21] BAMS-D has participated in CSG training events in the Virginia Capes operating area, including combined training unit exercises and joint task force exercises. Navy officials emphasized that Triton is a tactical asset and will respond to the requirements of the task force.

4497 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The Need for Interoperability

So far, this report has emphasized that home-station training is not as effective as it should be, thus reducing the effectiveness of multiservice, or interoperability, training at CTCs and during joint exercises. The importance of interoperability training is stressed in Chairman of the Joint Chiefs of Staff Guide 3501 (2012, pp. B-2 and B-3), which notes that the

> ability of systems, units, or forces to operate in synergy in the execution of assigned tasks is critical to successful operations. This ability to operate effectively together describes interoperability. From a joint training perspective, interoperability is a Service component responsibility. Interoperability training is based on joint doctrine, or where no joint doctrine exists, on Service or [SOF] doctrine to prepare forces or staffs from more than one Service component to respond to operational and tactical requirements deemed necessary by CCDRs [combatant commanders] to execute their assigned missions. Interoperability training involves forces of two or more Service components (including SOF) with no interaction with a CCDR or subordinate JFC [joint force commander] or joint staff.

The publication in 2011 of the MTTP for UASs was designed to address the problem of interoperability. As designed, it is

> a single source, descriptive reference guide to ensure effective planning, integration, and utilization of multi-service UAS capability. It provides commanders, operational staffs, requestors, and UAS operators with a comprehensive resource for planning and employing unmanned aircraft . . . . US Air Force (USAF) uses the term [RPA] for the air vehicle component of a UAS. (MTTP, 2011, p. i)

To date, interoperability training at the NTC and the Joint Readiness Training Center has been limited.[22] GAO (2005, p. 2) cited two significant challenges for improving interoperability training: (1) "establishing effective partnerships with program stakeholders through comprehensive communication and coordination and (2) developing joint training requirements that meet combatant commanders' needs," with particular emphasis on tactical level training (GAO, 2005, p. 2).[23] To meet this challenge, DoD established the Training Transformation Implementation Plan (Director, Readiness and Training Policy and Programs, 2006), giving the Office of the Under Secretary of Defense for Personnel and Readiness overall responsibility and giving the Deputy Under Secretary of Defense for Readiness executive agent responsibility for training transformation planning, programming, budgeting, and execution progress.

---

[22] GAO, 2005, p. 1, found that

> U.S. forces are conducting significantly more complex operations, requiring increased interoperability between and among the military services, combatant commands, and other DOD and non-DOD organizations. In the past, military services experienced some joint operations training during joint exercises, but most service training focused on individual service competencies with limited joint context.

[23] GAO, 2005, p. 18, noted that,

> in the past, joint training tasks were primarily focused at the command level and were identified through DOD authoritative processes that built requirements by translating command combat commanders inputs into training requirements. Training transformation has expanded joint training requirements to include those at the tactical level in addition to joint command level training.

4498 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

While RAND did not assess interoperability training in detail, discussions with the Army's training community, as noted above and as reported in GAO, 2010a, p. 26, suggest that such opportunities have been limited by the lack of Air Force assets, particularly the Predator, due to pressing operational requirements in Iraq and Afghanistan. The problem of transiting Air Force UAVs from Creech AFB to the NTC at Fort Irwin through FAA controlled airspace is often cited. Permanently stationing Air Force UAVs at the NTC would, of course, negate that problem, much as the Marine Corps has done by basing UASs at the MCAGCC at Twentynine Palms, California, to support training there. However, the experience of the Marine Corps suggests that the mere presence of UASs will not ensure that the forces are properly trained. The forces must prepare at their home stations for such training. In addition, given the common MTTP, forces trained to operate with their own services' UASs should find working with UASs from the other services less challenging.

Simulators

Congress has pressed for information on the role that simulators might play in a UAS training strategy, seeking an informed balance between live training and simulated training. In addition, the GAO reported that the

> military services lacked simulators that were capable of supporting training that is intended to build proficiency in skills required of UAS vehicle and sensor operators and prepare these personnel to conduct UAS combat missions. … [And] the Air Force and the Army have not fully developed comprehensive plans that address long-term UAS simulator requirements and associated funding needs. (GAO, 2010a, pp. 27–28)

Implicit in the GAO's comments is an assumption that simulators should play an important role in the future of UAS training. Our review questions that conclusion.

DoD has historically viewed simulator training and joint use of training facilities as an exercise in cost reduction. It is first necessary to understand how simulation better enables the introduction of the technology and, similarly, how joint use of the disruptive technology enables more effective military operations. For the purposes of this report, we have clearly focused on these aspects of simulation and jointness, which must be understood before the more-traditional perspectives of resource allocation can be applied. Currently, the usual significant savings that the department has garnered from simulators in the past do not appear to obtain in this instance. The danger is that, if the department starts with a savings orientation, it will not fully capitalize on the capabilities UASs represent.

For traditional aircraft systems, one major appeal of using simulators, rather than live flying, is the cost differential. For example, a RAND study of the trade-off between live and simulated training for manned aircraft noted that "the Marines and British are starting to give greater recognition to use of simulators as they seek either to reduce the high costs of live training or conserve the limited life of operational aircraft" (Schank et al., 2002, p. 49). In this case, the cost of flying the strike fighter aircraft they were discussing was many times greater than the cost of using a simulator, and the procurement cost of the aircraft itself was also significantly greater than that of the simulator. That said, they also noted that,

4499 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

> [t]o increase that use, several improvements must happen to integrate simulators more fully into their unit training. The fidelity and availability of simulators must increase to the point that fighter pilots see their benefit in training. This requires additional funding for simulators. (Schank et al., 2002, p. 49)

The report further argues that, even given the cost advantage of simulators for strike fighter aircraft training, simulators are a complement to live training, not a substitute for it.

The same point was made to us concerning UAS simulators. Officials of the 432d Wing also noted that simulators were not very good for training on landings. Moreover, a substantial investment in new simulator technology would be necessary to improve the realism of UAS simulators to the point it could prove useful for training UAS crews and ground forces. For example, GAO, 2010a, p. 28, found that currently Air Force and Army simulators did not have the ability

> to replicate all UAS procedures and to enable the integration of UAS training with other types of aircraft, [e.g.,] … the Army's Shadow Institutional Mission Simulator is not currently capable of replicating system upgrades that are being fielded directly to ongoing combat operations, such as a laser target designator and communications relay equipment. … Air Force and Army simulators are also … incapable of providing virtual, integrated training opportunities between manned and unmanned aircraft because of interoperability and information security concerns.

The conditions that make a compelling case for simulators for the training of fighter pilots are largely absent when it comes to UAS training:

- First, UAS flying hours are much less expensive than flying hours for manned aircraft. By one account, the flying hour cost of Shadow was $705; a comparable figure for Gray Eagle was $4,275.[24] By comparison, the Air Force told the GAO that "the live training cost of one F-15E flight hour is approximately $17,449" (Pickup, 2012, pp. 15–16). Other sources peg the flying hour costs of manned aircraft much higher.[25]
- Second, the kinds of operational activities that need more training emphasis, in particular, air-ground coordination, are generally not activities in which simulators *per se* can substitute for live flying. A good example of both the limitations and the value of simulators can be found at the digital air-ground integration ranges the Army operates today. On these ranges, only the weapon system engagement is simulated. Everything else—planning, coordination, UAS operation, ground unit and/or manned aircraft activity, target acquisition—is live.
- Third, while simulators are inherent in the systems used for initial training of pilots and sensor operators,[26] they are not well suited (and not designed) for training operating

[24] Ron Moring, UAS cost per flying hours, personal communication, April 5, 2013. The cost for the Gray Eagle is similar to the costs the Air Force reported for Predator at $3,679 and Reaper at $4,762, as reported by Mark Thompson, "Costly Flight Hours," *Time*, April 2, 2013.

[25] Recently, the Air Force comptroller's office told *Time* that the flying hour cost for the F-15C was $41,921. Other aircraft had considerably higher flying hour costs; e.g., the cost of flying an F-22 for one hour was reported to be $68,362. See Thompson, 2013.

[26] See Shawn Johnson, DAMO-TRC Army Flying Hour Program, "UAS cost per flying hours," personal communication, with Joan Vandervort, Office of the Office USDP&R, April 10, 2013.

4500 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

forces on the full spectrum of UAS capabilities. Simulators may be useful as a supplement to live training of pilots and crews but do not replicate the myriad activities and stimuli that a live training environment provides well for maneuver forces.
- Fourth, as noted previously, simulators at best complement rather than substitute for live training. Given the current state of UAS fielding, first priority must be given to building the live-flying infrastructure. Then, and only then, might funds be used to undertake the research and development that must precede any consideration of fielding the kind of interactive UAS air-ground simulators that could train both UAS crews and ground troops.

In the future, the services should reevaluate the need for virtual training using a cost and effectiveness analysis (COEA) including developmental costs for simulators, the savings based on the costs of flying UASs, and the critical availability of air space for training. Given current budget limitations and the importance of fully developing the opportunities for live training and the relatively low cost of such training, diversion of funds to a research and development program to develop higher-fidelity UAS-ground simulators is not appropriate at this time.

Summary

This chapter presented an overview of UAS training in 2012. Our focus was on service-specific and interoperability training. The training framework presented in Chapter Three was our starting point, with an emphasis on preparing forces for joint training and deployment. We looked at ground, air, and sea forces. Insights came from a wide variety of sources but mainly through visits to selected service bases, where we talked with operators and support personnel, those who train operators and associated team members, and those who train and observe the forces who employ UASs. In general, the RAND team found that qualification training in all the services for designated UAS-specific MOSs is well established. The critical issue is being able to train with ground forces at home station. The experience of the Marine Corps illustrates the importance of such opportunities. The Marine Corps has Shadow squadrons based at the MCAGCC at Twentynine Palms, California, where the restricted airspace is adequate both for maintaining crew proficiency and for supporting ground forces. However, both the ground trainers and squadron personnel the RAND team interviewed reported that the ground forces are not adequately trained at home station to integrate UAS capabilities into their operations. This required starting with what amounted to "remedial" training at Twentynine Palms, and trainees thus did not achieve the level of proficiency desired. This suggests that the biggest challenge in developing and implementing a training strategy for UASs is gaining and maintaining proficiency on the part of end users or "supported units"—the leaders and staffs who will integrate UAS capabilities into their operations.

Thus, as the war in Afghanistan draws to a close, the services must pay close attention not only to training UAS crews and support personnel but also to routinely exercising these systems during combined arms training at home station and at the CTCs. We addressed a number of issues for this, including beddown and support facilities and airspace considerations.

We found that home station training is generally not as effective as it should be, thus reducing the potential effectiveness of multiservice or "interoperability" training at CTCs and during joint exercises. We noted that, to date, interoperability training at the CTCs has been

4501 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

limited by the lack of Air Force assets, particularly the Predator, due to pressing operational requirements in Iraq and Afghanistan. However, given the common MTTP, forces trained to operate with their own service UASs should find working with UASs from the other services less challenging.

Finally, we considered the case for UAS simulators. Currently, such simulators do not appear to offer the significant savings that the Department has usually garnered from simulation in the past. We concluded that, given current budget limitations and the importance of fully developing the opportunities for live training and the relatively low cost of such training, diversion of funds to a research and development program to develop higher fidelity UAS-ground simulators would be unwise at this time.

4502 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

CHAPTER FIVE

Implications and Recommendations

The Guiding Principle: "Train As We Fight"

DoD has been under some pressure from Congress and such organizations as GAO for the lack of central control and the lack of the development of a joint DoD strategy for training. For example, "DOD Lacks a Comprehensive, Results-Oriented Strategy to Resolve UAS Training Challenges," was the summary title of a section of a recent GAO report (GAO, 2010a, p. 29). The Joint Unmanned Aircraft System Center of Excellence was established to support the joint operator and the services by facilitating the development and integration of common unmanned aircraft system operating standards, capabilities, concepts, technologies, doctrine, tactics, techniques, procedures, and training. The center, however, was disestablished in May 2011, and its UAS oversight function was reassigned to the Joint Staff Force Structure, Resources, and Assessment Directorate (J8), with some responsibilities assigned to the UAS Task Force. However, the 2011 publication of the MTTP for UASs addressed the problem of interoperability, and the services have agreed to incorporate the MTTP in their training.
While the services have agreed to a common set of TTP, each service continues to develop its own UASs to meet its own requirements. Moreover, the GAO (2010a, p. 25) has well documented that the opportunity for joint training is limited. While the GAO identified a number of organizations and initiatives addressing UAS training challenges, only one of the eight organizations and initiatives it listed were led by the services. Given the current maturation of UAS platforms, this emphasis is misplaced; the military services employs their UASs in very different ways. Today, the services are still struggling with how to incorporate these new systems. The appropriate strategy for UAS training is to encourage each service to solve its own UAS training problems, then to coordinate the resulting TTPs by updating the MTTP to achieve a high level of interoperability.

Commanders and operators from the bottom up are discovering and adapting to the revolutionary operational changes that UASs have brought about. The most apparent changes are in the persistence and responsiveness of UASs relative to other platforms in the permissive threat environments in which they are currently operating. These characteristics help develop valuable shared situational awareness between UASs and the supported forces and also make ISR capabilities more responsive and immediately available. Processing, exploitation, and dissemination concepts for UAS-generated information, however, are still evolving. In addition, armed UASs provide strike capabilities similar in some ways to those of CAS; the evolution of UASs from pure ISR platforms to small, lightly armed ISR platforms, to bigger, more heavily armed, faster, and even stealthier reconnaissance-strike platforms has crossed operational and cultural seams. This has lead to the need for continual resolution of disputes between intelli-

4503 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

gence and operations staffs over priorities for UASs and their implications for mission planning and execution.

To date, the services have, in a variety of important ways, been "training *while* they fight." Iraq and Afghanistan have served as de facto training ranges, as well as an active theater of war. For example, Air Force Predator and Reaper pilots and sensor operators have frequently gone straight from flight instruction and certification to flying real-world missions, learning and adapting as they support operations. Army and Marine Corps units have also learned in theater how to capitalize on the robust set of capabilities UASs provide.

The demonstrated ability of the services to learn on the fly should be cause for optimism about continued success in UAS training as operations wind down. But that continued success will depend on preserving training opportunities in an environment in which training is not an incidental by-product of operational requirements. Operational experiences, for example, typically do not suffer from the inherent limitations of CONUS training venues, such as limited area, limited time, and limited fidelity. Because of such limitations, it has been harder to train as we fight in CONUS. Infrastructure and other limitations currently make it difficult or impossible to train at night or in bad weather, to train with live or dummy munitions, or to train in a communications environment that represents the environment and demands of actual operations in theater. Preservation of the current levels of proficiency, improvement where needed, and adaptation to changing circumstances will not come without effort; they will require overcoming or at least alleviating the limitations mentioned here.

Elements of a Strategic Training Plan

To *train as we fight*, the DoD training strategy must

- engender better appreciation of UAS capabilities throughout the chain of command
- address organizational, structural, and infrastructure and support issues
- enable training as we fight in collective unit training
- enable training as we fight in larger exercises.

Engender Better Appreciation of UAS Capabilities

Many ground force commanders and their battle staffs today do not fully recognize the potential benefits UASs bring to the fight and, as a result, are not in a position to benefit from them in circumstances that would improve units' warfighting capabilities. This is traceable in part to limited use of UASs in home-station and CTC training but also to other inherent limitations, such as a shortage of experienced personnel and UAS assets and airspace and infrastructure limitations. Overcoming these limitations will enable more opportunities to foster better understanding and improve integration. Training guidance should emphasize the value of UASs, using examples of how units have benefited by preparing themselves to use such systems through training and attending familiarization courses. Such vignettes can be inserted into professional education and training materials to share positive experiences working with UASs.

4504 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Address Organizational, Structural, and Training Infrastructure and Support Issues

Organization and Structure

UASs are a disruptive technology, and their introduction can create tensions between operations and intelligence staffs on the right balance between using UASs to collect intelligence or launch strikes. In the Army, for example, one could ask, is Gray Eagle an ISR asset or an armed reconnaissance system? Doctrine development efforts should produce a doctrine flexible enough to allow changes in allocation and organizational balances and address the attendant training issues accordingly.

Also, in the Army, the organizational placement of UASs remains a challenge, as illustrated by the fact that the assignment of responsibilities for the Raven is still being worked out. A more-systematic approach to monitoring and maintaining Raven operator qualifications will better enable integration of the system into maneuver forces and thus improve overall training and help develop better appreciation of the system's capabilities and limitations. In addition, the Army is currently examining alternatives for placing Shadow platoons in the headquarters company of a brigade combat team or consolidating them in the developing full-spectrum combat aviation brigade. Resolution of these organizational issues will likewise aid in training integration.

Training Infrastructure, Training Support Issues, and Related Factors

Some of the most important ways in which shortfalls can detract from UAS training are

- incompatible or different communications capabilities
- airspace restrictions
- inability to train at night or in bad weather
- inability to use live or dummy munitions
- UAS unavailability
- insufficient time.

These shortfalls cannot always be fully corrected. Some, such as differences in communications capabilities, are inherent but can be alleviated to some extent. The full correction of others may be unaffordable, but partial correction should still be possible. Inability to train at night or in bad weather, for example, is to some extent a result of FAA restrictions on when Air Force UASs can fly from their bases to the NTC. Basing Air Force UASs at the NTC would significantly reduce the effect of these restrictions and might also make it possible for the UASs to use live or dummy munitions, further improving realism for both customers and operators.

Research suggests that airspace restrictions, while sometimes nettlesome, need not pose a serious obstacle to most UAS training at a unit's home station, either for operators or end users. Nevertheless, efforts to gain more access to airspace should continue with the research and development of the joint program for GBSAA systems, led by the Army's program manager for UAS. This system uses ground-based radars to provide an extra layer of airspace safety, which could enable the FAA to make the use of civil airspace adjacent to UAS training airspace less restrictive and thus expand the airspace available for UAS training. A promising initial demonstration with Gray Eagle took place in summer 2011, but GBSAA is not expected to be certified for use until 2015.

The insufficient number of UASs for training should be alleviated to some extent as some systems redeploy from overseas theaters and also by the recent decision to increase the number

4505 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

of Predator/Reaper CAPs from 61 available today to 85 in the future. Similarly, the Operation Enduring Freedom drawdown will likely free up more RPA trainers, alleviating the shortfall.

Enable Training as We Fight in Unit Collective Training

To facilitate home station training, the following steps need to be taken:

- Training must make full use of units' UASs and must use simulation or surrogates, despite their limitations, when live use is not possible.
- Training should include the systems of other services and their associated joint tactical air controllers (JTACs) and air liaison officers (ALOs) to the extent possible.
- Air Force preparation training of JTACs and ALOs should be available for support of unit-level training, as well as for larger exercises.
- After-action reviews and reports should be expanded to reinforce lessons learned; they can also provide a sound basis for continued measurable improvements. Over time, the reports growing out of these documents should become more detailed and should incorporate measures of performance and effectiveness, so that these metrics can drive future improvements.

Enable Training as We Fight in Larger Exercises

By design, larger exercises like those at maneuver CTCs provide considerable opportunities for more-realistic training. They are thus already better postured to provide training on the use and integration of UAS. However, more can be done to enhance the use of training opportunities in such large exercises to further the goal of better UAS integration in the force. Specifically, we recommend

- continued stress on training realism
- including live UASs and their associated JTACs and ALOs as much as possible
- including the CAS-like and ISR missions that UASs, especially Air Force UASs, will be performing in theater
- providing a small paved air strip to base RPAs, launch and recovery elements (LREs), and support crews at the maneuver CTCs to avoid the NAS constraints associated with remote operation
- continued efforts to integrate additional Creech AFB–based UASs into CTC training, when needed.

Initiatives with Likely Near-Term Payoffs

Other things can be done that should provide near-term payoffs:

- **Increase exposure to the capabilities and limitations of UAS—**Continue to expose appropriate commanders to UAS operations through short (one- to two-day) familiarization courses, such as those the Air Force offers at various UAS squadrons' locations (e.g., Creech AFB, Beale AFB, and March ARB). These also need to be introduced as part of the joint training curriculum in a more formal and standardized fashion across the force. The proliferation of Air Force UAS squadrons geographically within CONUS should provide ready access for ground units whatever their home station.

4506 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

- **Harness the lessons-learned process to guide the development of service and joint doctrine and TTP—**Formalize and standardize these processes as appropriate, and share best practices more extensively across services and regions. Right now, most extended learning is done "on the job," with lessons learned shared informally among operators and trainers. Different UAS elements tend to focus support on different ground units, each with geographical and other mission differences. Best practices across these geographic and mission boundaries need to be understood to inform joint doctrine and, hence, responsive training requirements.
- **Address well-known but underresourced training infrastructure shortfalls—**Consider this issue in light of our previous discussions of basing. UASs can be based at maneuver CTCs to minimize the impact of FAA restrictions. If this is done as a part of the drawdown and redeployment of RPA units to CONUS, this should not be too disruptive or expensive; many details remain to be worked out, but military construction and other costs appear to be manageable. Communications infrastructure and C2 organizations and processes at the ranges can be enhanced to better mirror operational capabilities.

Institutionalizing Training for UAS Capabilities over the Longer Term

Institutionalizing UAS training over the longer term will naturally depend on continued support for the specific programs and initiatives and others like them that we outlined earlier. Institutionalization will also require more-general efforts, falling into three broad categories: acculturation, professional development of the UAS force (operators, maintainers, and a UAS chain of command), and integration of the UAS community (a subprofession, if you will) into the aviation profession. These three are somewhat interwoven, and the third depends on the first two. Finally, institutionalization over the longer term will require adaptation: The strategies must be designed to be adaptive, and those who develop and implement them must be willing to adapt them.

Acculturation

The RAND team heard from many sources that many end users do not yet have a well-developed appreciation of the capabilities UASs can bring to an operation. In some cases, this lack of appreciation has derived from negative experiences. Some of these experiences resulted from inexperienced operators, some from mechanical failures, some from sheer bad luck (e.g., weather). The need to deconflict airspace and the need to do so, even when using restricted airspace reserved for military use, often led to utilization problems and contributed to negative impressions about the value of UAS. First impressions do count, and avoiding bad ones is much easier than overcoming them later.

Professional Development

All the services need to maintain professional development strategy for the UAS force. The services are developing a professional force of operators for UASs, both systems and payloads, consisting of enlisted soldiers, noncommissioned officers, and warrant and commissioned officers, although the Army currently has no UAS officer specialty. It is important to develop a cadre of UAS professionals with hands-on experience in all echelons of UAS operation; the Army may

4507 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

wish to consider a career pipeline for such officers, perhaps with an additional skill identifier. Such a professional cadre is a key element in full integration of UAS capabilities.

Integration

The services are making significant efforts to integrate UASs into their force structures. Army efforts would be aided by more access during training to the operational and even strategic capabilities of Air Force UASs. These efforts will be aided by better acculturation and an institutionalized UAS career field that, over time, develops professionals with a more-complete understanding of UAS capabilities and limitations and sufficient rank, technical expertise, and operational experience to enable better integration of the capabilities into the overall operations of the end users. Related issues include integration of UAS capabilities with other ISR systems and with the intelligence warfighting function more generally, the tension between those who value the strike capabilities of UASs and those who value the intelligence collection capabilities, and the further tensions likely to emerge as UAS capabilities widen further. As UAS capabilities grow and broaden, integrating them into other warfighting functions will also present challenges.

Adaptation

The training strategy must adapt to future technical innovations and changes in operational demands. To enable this adaptability, those concerned with overall training strategy development will need to remain cognizant of and to guide the following, where possible:

- evolution of the roles of UASs in the full range of military operations, and the speed and breadth of the expansion of those roles
- surfacing and resolving UAS doctrinal issues (In particular, how will the requirements of intelligence and operations be integrated and deconflicted? How will both organic and nonorganic systems be better integrated to support ground forces, and which warfighting functions will they support? How will technological advances and changes in expected operational conditions influence decisions regarding these roles and missions?)
- service adjustments of force structures and personnel management processes to accommodate the disruptive technology effects of UASs
- influence of the above and related issues on the development, promulgation, and adaptation of joint and service doctrines so these doctrines can continue to form a solid basis for UAS training.

Summary of Findings and Recommendations

Our findings and recommendations are summarized as follows:

1. The proper strategy for DoD at this time is to encourage each service to solve its own UAS training problems, rather than to constrain any one service under the guise of joint operations.
2. DoD should support current and future programs to develop ranges and beddown and support facilities similar to those in the Army's current programs.

4508 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

3. In spite of the demands of deploying units and sustaining combat operations in Afghanistan, Army trainers indicate that Army units are better at maintaining qualification for Shadow qualification than for Raven. Nevertheless, not all units have been able to maintain high Shadow qualification rates—some units arrive at the NTC with one-half or fewer of their operators qualified. Better tracking of operators and their sustainment training is needed, particularly but not exclusively for Ravens.
4. If joint training becomes a priority, the Air Force's current basing and beddown posture will become more of a problem. The Air Force could consider the location of Army hubs when choosing where to base its UAS fleet. A location that is near Army maneuver elements might make airspace access less of a restriction or at least make COAs more practical. Proximity might provide more opportunities for training UAS integration throughout the entire mission planning process.
5. Given current budget limitations and the importance of fully developing the opportunities for live training and the relatively low cost of such training, diversion of funds to a research and development program to develop higher fidelity simulators would seem unwise at this time.

Path to the Future

We have presented and discussed a multitude of means for setting up UAS training strategies for success. These means include support for ongoing facilities and basing initiatives; expansion of such facilities, where possible, to enable wider availability of UASs to support collective training; and efforts to increase the use of UASs—the complete UAS package, including JTACs and other coordinating elements—in collective training, both local and in larger exercises. We have noted the need to support continuing efforts to resolve airspace access issues, observing as we did so that there are ways to keep such restrictions from imposing serious limitations on much of the UAS training envisioned here. Similarly, we have discussed the potential for simulators to add value in training, now and perhaps more in the future. But we have also cautioned that simulators, in their current state, are not a good substitute for live use of UASs in collective training.

The path to the future for UAS strategies starts now, with support for ongoing initiatives that will continue the trends towards better training integration and thus better ability on the part of end users to employ the multiple capabilities of UASs in their operations. The path continues, using that foundation, with longer-term efforts to add to acculturation of end users, professionalization of the UAS community, and integration of the two to harmonize the capabilities of UASs as key elements of overall force effectiveness.

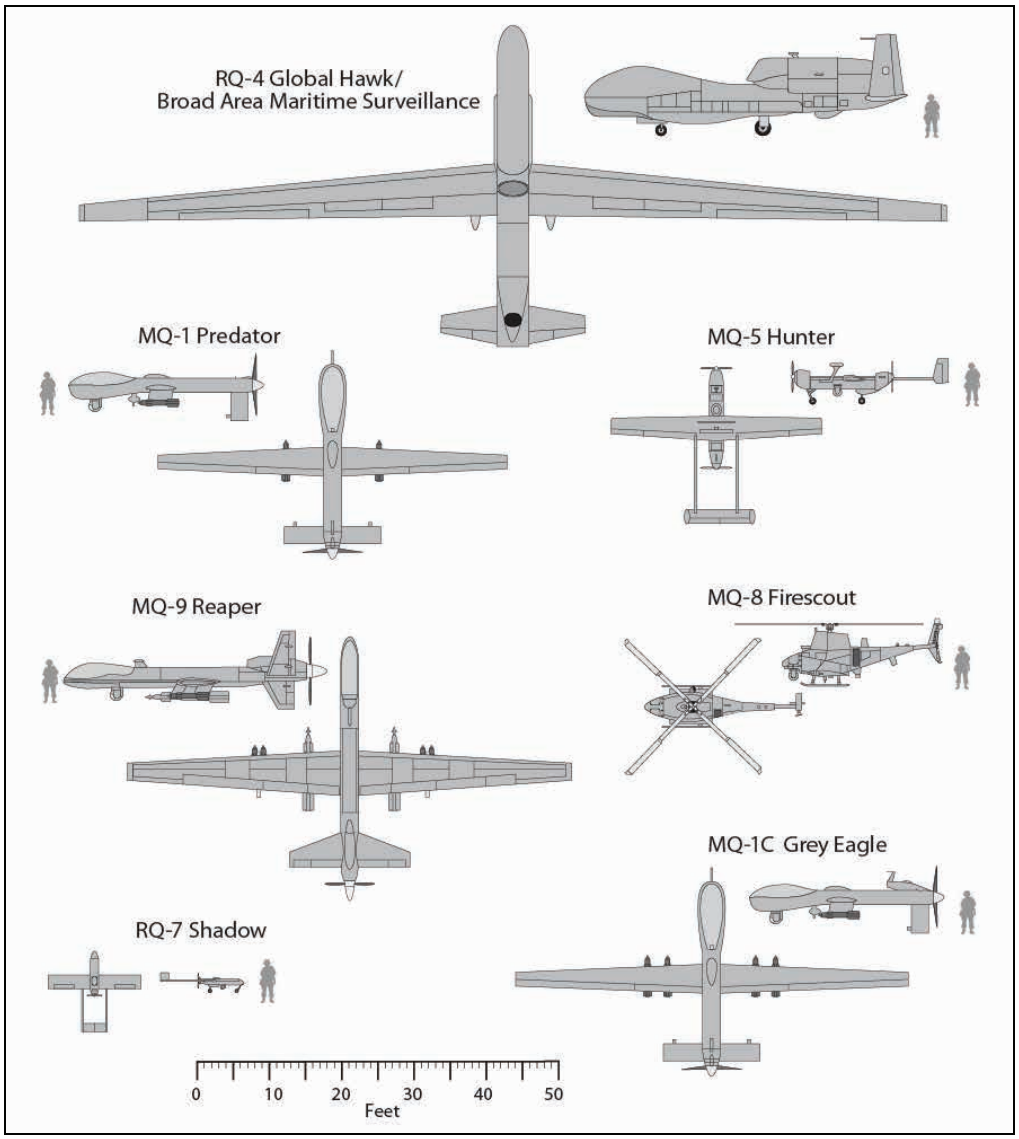
APPENDIX A

Current Major DoD UAS Programs in FY 2012

The following pages come directly from a Congressional Research Service report on U.S. UASs (Gertler, 2012, pp. 31–46).

4511 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Current Major DOD UAS Programs



This section addresses the program status and funding of some of the most prominent UAS programs being pursued by DOD, and most likely to compete for congressional attention. This section does not attempt to provide a comprehensive survey of all UAS programs, nor to develop a classification system for different types of UAS (e.g., operational vs. developmental, single mission vs. multi mission, long range vs. short range). One exception is a short subsection below titled "Small UAVs." The UAVs described in this section are distinguished from the proceeding UAVs by being man-portable and of short range and loiter time. These smaller UAVs are not currently, and are unlikely to be, weaponized. The services do not provide as detailed cost and budget documentation for these UAVs as they do for major UAS programs. Individually, these UAVs appear very popular with ground forces, yet do not necessarily demand as much congressional attention as larger UAS programs like Predator or Global Hawk. As a whole, however, these small, man-portable UAVs appear likely to increasingly compete with major UAS programs for congressional attention and funding.

Table 6. Characteristics of Selected Tactical and Theater-Level Unmanned Aircraft

System	Length (ft)	Wingspan (ft)	Gross weight (lbs)	Payload capacity (lbs)	Endurance (hours)	Maximum altitude (ft)
Predator	27	55	2,250	450	24+	25,000
Grey Eagle	28	56	3,200	800	40	25,000

Source: Congressional Budget Office based on data from the Department of Defense's budget request for 2012, Selected Acquisition Reports for December 2010, and Aircraft Procurement Plan: Fiscal Years 2012-2041 (submitted with the 2012 budget, March 2011).

Notes: Acquisition cost includes the cost of procuring air vehicles, sensors, and grounds stations, plus the cost for research. development, test, and evaluation. The services' cost data have been adjusted using CBO's projection of inflation and rounded to the nearest $10 million.

a. The Department of Defense has no plans to acquire or modify the specified system in these years.

b. The cost is for the follow-on aircraft the Air Force plans to acquire instead of the Reaper.

MQ-1 Predator

Through its high-profile use in Iraq and Afghanistan and its multi-mission capabilities, the MQ-1 Predator has become the Department of Defense's most recognizable UAS. Developed by General Atomics Aeronautical Systems in San Diego, CA, the Predator has helped to define the modern role of UAS with its integrated surveillance payload and armament capabilities. Consequently, Predator has enjoyed accelerated development schedules as well as increased

4514 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

procurement funding. The wide employment of the MQ-1 has also facilitated the development of other closely related UAS (described below) designed for a variety of missions.

System Characteristics. Predator is a medium-altitude, long-endurance UAS. At 27 feet long, 7 feet high and with a 48-foot wingspan, it has long, thin wings and a tail like an inverted "V." The Predator typically operates at 10,000 to 15,000 feet to get the best imagery from its video cameras, although it has the ability to reach a maximum altitude of 25,000 feet. Each vehicle can remain on station, over 500 nautical miles away from its base, for 24 hours before returning home. The Air Force's Predator fleet is operated by the 15th and 17th Reconnaissance Squadrons out of Creech Air Force Base, NV; the 11th Reconnaissance Squadron provides training. A second control station has been established at Whiteman AFB, MO.[104] Further, "[t]here are plans to set up Predator operations at bases in Arizona, California, New York, North Dakota, and Texas."[105] The Air Force has about 175 Predators;[106] the CIA reportedly owns and operates several Predators as well.

Mission and Payload. The Predator's primary function is reconnaissance and target acquisition of potential ground targets. To accomplish this mission, the Predator is outfitted with a 450-lb surveillance payload, which includes two electro-optical (E-O) cameras and one infrared (IR) camera for use at night. These cameras are housed in a ball-shaped turret that can be easily seen underneath the vehicle's nose. The Predator is also equipped with a Multi-Spectral Targeting System (MTS) sensor ball which adds a laser designator to the E-O/IR payload that allows the Predator to track moving targets. Additionally, the Predator's payload includes a synthetic aperture radar (SAR), which enables the UAS to "see" through inclement weather. The Predator's satellite communications provide for beyond line-of-sight operations. In 2001, as a secondary function, the Predator was outfitted with the ability to carry two Hellfire missiles. Previously, the Predator identified a target and relayed the coordinates to a manned aircraft, which then engaged the target. The addition of this anti-tank ordnance enables the UAS to launch a precision attack on a time sensitive target with a minimized "sensor-to-shoot" time cycle. Consequently, the Air Force changed the Predator's military designation from RQ-1B (reconnaissance unmanned) to the MQ-1 (multi-mission unmanned).[107] The air vehicle launches and lands like a regular aircraft, but is controlled by a pilot on the ground using a joystick.

MQ-1C Grey Eagle

A slightly larger, longer-endurance version of the Predator, the Army's MQ-1C Grey Eagle entered low-rate initial production on March 29, 2010.[108] The Grey Eagle can remain aloft for 36 hours, 12 hours longer than its Air Force sibling.

An Army platoon operates four aircraft with electro-optical/infrared and/or laser rangefinder/designator payloads, communications relay equipment, and up to four Hellfire

4515 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

missiles. Each platoon includes two ground control stations, two ground data terminals, one satellite communication ground data terminal, one portable ground control station, one portable ground data terminal, an automated takeoff and landing system, two tactical automatic landing systems, and ground support equipment. In total, the program will be 124 aircraft, plus 21 attrition aircraft and 7 schoolhouse aircraft, for a total of 152 aircraft. The average procurement unit cost of a Grey Eagle system is $114.1 million.[109]

MQ-9 Reaper

The MQ-9 Reaper, formerly the "Predator B," is General Atomics' follow-on to the MQ-1. The Reaper is a medium- to high-altitude, long-endurance Predator optimized for surveillance, target acquisition, and armed engagement. While the Reaper borrows from the overall design of the Predator, the Reaper is 13 feet longer and carries a 16-foot-longer wingspan. It also features a 900 hp turboprop engine, which is significantly more powerful than the Predator's 115 hp engine. These upgrades allow the Reaper to reach a maximum altitude of 50,000 feet, a maximum speed of 225 knots, a maximum endurance of 32 hours, and a maximum range of 2,000 nautical miles.[110] However, the feature that most differentiates Reaper from its predecessor is its ordnance capacity. While the Predator is outfitted to carry 2 100-pound Hellfire missiles, the Reaper now can carry as many as 16 Hellfires, equivalent to the Army's Apache helicopter, or a mix of 500-pound weapons and Small Diameter Bombs.

As of February 4, 2011, General Atomics Aeronautical Systems had delivered 65 of 399 planned Reapers, 43 of which are operationally active.[111]

The MQ-9 is operated by the 17th Reconnaissance Squadron and the 42nd Attack Squadron, both at Creech Air Force Base, NV, and the 29th Attack Squadron at Holloman AFB, NM.[112]

Program Status. Predator–family UAS are operated as part of a system, which consists of four air vehicles, a ground control station, and a primary satellite link. The unit cost in FY2009 for one Predator system was approximately $20 million,[113] while the average procurement unit cost for a Reaper system was $26.8 million.[114]

RQ-4 Global Hawk

Northrop Grumman's RQ-4 Global Hawk has gained distinction as the largest and most expensive UAS currently in operation for the Department of Defense. Global Hawk incorporates a diverse surveillance payload with performance capabilities that rival or exceed most manned spy planes. However, Pentagon officials and Members of Congress have become increasingly concerned with the program's burgeoning cost, which resulted in Nunn-McCurdy breaches in April 2005 and April 2011.[115] Also, the RQ-4B Block 30 was deemed "not operationally suitable" due to "low air vehicle reliability" by the office of Operational Test and Evaluation in May 2011.[116]

System Characteristics. At 44 feet long and weighing 26,750 lbs, Global Hawk is about as large as a medium sized corporate jet. Global Hawk flies at nearly twice the altitude of commercial airliners and can stay aloft at 65,000 feet for as long as 35 hours. It can fly to a target area 5,400 nautical miles away, loiter at 60,000 feet while monitoring an area the size of the state of Illinois for 24 hours, and then return. Global Hawk was originally designed to be an autonomous drone capable of taking off, flying, and landing on pre-programmed inputs to the UAV's flight computer. Air Force operators have found, however, that the UAS requires frequent intervention by remote operators.[117] The RQ-4B resembles the RQ-4A, yet features a significantly larger airframe. In designing the B-model, Northrop Grumman increased the Global Hawk's length from 44 feet to 48 feet and its wingspan from 116 feet to 132 feet. The expanded size enables the RQ-4B to carry an extra 1000 pounds of surveillance payload.

[115] Amy Butler, "USAF Declares Second Major Global Hawk Cost Breach," Aerospace Daily, April 13, 2011. The 2005 breach stemmed from costs in transitioning from the Block 10 Global Hawk to the larger Block 30; the 2011 breach was attributed primarily to reduced procurement quantities rather than issues with the program.

[117] Jeff Morrison, "USAF No Longer Viewing Global Hawk As An Autonomous System, Official Says," *Aerospace Daily*, December 3rd, 2005.

4517 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Mission and Payload. The Global Hawk UAS has been called "the theater commander's around-the-clock, low-hanging (surveillance) satellite."[118] The UAS provides a long-dwell presence over the battlespace, giving military commanders a persistent source of high-quality imagery that has proven valuable in surveillance and interdiction operations. The RQ-4A's current imagery payload consists of a 2,000-lb integrated suite of sensors much larger than those found on the Predator. These sensors include an all-weather SAR with Moving Target Indicator (MTI) capability, an E-O digital camera and an IR sensor. As the result of a January 2002 Air Force requirements summit, Northrop Grumman expanded its payload to make it a multi-intelligence air vehicle. The subsequent incarnation, the RQ-4B, is outfitted with an open-system architecture that enables the vehicle to carry multiple payloads, such as signals intelligence (SIGINT) and electronic intelligence (ELINT) sensors. Furthermore, the classified Multi-Platform Radar Technology Insertion Program (MP-RTIP) payload will be added in order to increase radar capabilities. These new sensor packages will enable operators to eavesdrop on radio transmissions or to identify enemy radar from extremely high altitudes. Future plans include adding hyper-spectral sensors for increased imagery precision and incorporating laser communications to expand information transfer capabilities.[119] The end goal is to field a UAS that will work with space-based sensors to create a "staring net" that will prevent enemies from establishing a tactical surprise.[120] In August 2003, the Federal Aviation Administration granted the Global Hawk authorization to fly in U.S. civilian airspace, which further expanded the system's mission potential.[121] This distinction, in combination with the diverse surveillance capabilities, has led many officials outside the Pentagon to consider the Global Hawk an attractive candidate for anti-drug smuggling and Coast Guard operations.[122]

Program Status. Developed by Northrop Grumman Corporation of Palmdale, CA, Global Hawk entered low-rate initial production in February 2002. The Air Force has stated that it intends to acquire 51 Global Hawks, at an expected cost of $6.6 billion for development and procurement costs. As of November 2009, the Air Force possessed 7 RQ-4As and 3 RQ-4Bs.[123] Another 32 Global Hawks had been authorized and appropriated through FY2011.[124] According to the most recent Selected Acquisition Report, the current average procurement unit cost for the Global Hawk has reached $140.9 million in current dollars.[125]

In April 2005, the Air Force reported to Congress that the program had overrun by 18% as a result of an "increasing aircraft capacity to accommodate requirements for a more sophisticated, integrated imagery and signals intelligence senor suite."[126] A Government Accountability Office report in December 2004 noted that the program had increased by nearly $900 million since 2001 and recommended delaying the purchase of future Global Hawks until an appropriate

4518 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

development strategy could be implemented.[127] The rising costs of the UAV and accusations of Air Force mismanagement have caused concern among many in Congress and in the Pentagon as well as facilitating an overall debate on the Air Force's development strategy.[128]

Following a 2010 Defense Acquisition Board review of the Global Hawk program,

> Air Force acquisition executive David Van Buren told reporters that he is "not happy" with the pace of the program, both on the government and the contractor side. Chief Pentagon arms buyer Ashton Carter also criticized the program, saying that it was "on a path to being unaffordable."[129]

In April 2011, a reduction in the number of Global Hawk Block 40 aircraft requested in the FY2012 budget from 22 to 11 caused overall Global Hawk unit prices to increase by 11%, again triggering Nunn-McCurdy.[130]

In its markup of the FY2011 defense authorization bill, the House Armed Services Committee expressed concern "that differing, evolving service unique requirements, coupled with Global Hawk UAS vanishing vendor issues, are resulting in a divergence in each service's basic goal of maximum system commonality and interoperability, particularly with regard to the communications systems." The bill report directs the Under Secretary of Defense for Acquisition, Technology, and Logistics to certify and provide written notification to the congressional defense committees by March 31, 2011, that he has reviewed the communications requirements and acquisition strategies for both Global Hawk and BAMS. The subcommittee wants assurance that the requirements for each service's communications systems have been validated and that the acquisition strategy for each system "achieves the greatest possible commonality and represents the most cost effective option" for each program.[131]

A May 20, 2011, report from the Air Force Operational Test and Evaluation Center found the Global Hawk Block 20/30 to be "effective with significant limitations ... not suitable and partially mission capable." The report cited "lackluster performance of the EISS imagery collector and ASIP sigint collectors at range" rather than issues with the Global Hawk airframe itself.[132]

[130] The Nunn-McCurdy provision requires DOD to notify Congress when cost growth on a major acquisition program reaches 15%. If the cost growth hits 25%, Nunn-McCurdy requires DOD to justify continuing the program based on three main criteria: its importance to U.S. national security; the lack of a viable alternative; and evidence that the problems that led to the cost growth are under control. For more information, see CRS Report R41293, *The Nunn-McCurdy Act: Background, Analysis, and Issues for Congress* , by Moshe Schwartz.

BAMS

The Navy's Broad Area Maritime Surveillance system is based on the Global Hawk Block 20 airframe but with significantly different sensors from its Air Force kin. This, coupled with a smaller fleet size, results in a higher unit cost. "The air service's drone costs $27.6 million per copy, compared to an expected $55 million per BAMS UAV, including its sensors and communications suite…. At 68 aircraft, the BAMS fleet will be the world's largest purchase of long-endurance marinized UAVs."[133]

System Characteristics and Mission. "BAMS ... provides persistent maritime intelligence, surveillance, and reconnaissance data collection and dissemination capability to the Maritime Patrol and Reconnaissance Force. The MQ-4C BAMS UAS is a multi-mission system to support strike, signals intelligence, and communications relay as an adjunct to the MMA/P-3 community to enhance manpower, training and maintenance efficiencies worldwide."[134]

"The RQ-4 ... features sensors designed to provide near worldwide coverage through a network of five orbits inside and outside continental United States, with sufficient air vehicles to remain airborne for 24 hours a day, 7 days a week, out to ranges of 2000 nautical miles. Onboard sensors will provide detection, classification, tracking and identification of maritime targets and include maritime radar, electro-optical/infra-red and Electronic Support Measures systems. Additionally, the RQ-4 will have a communications relay capability designed to link dispersed forces in the theater of operations and serve as a node in the Navy's FORCEnet strategy."[135]

[135] Department of Defense, *Department of Defense Fiscal Year 2012 Budget Estimates, Research, Development, Test & Evaluation, Navy*, Budget Activity 7, February 2011.

4520 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

"The drones ... will collect information on enemies, do battle-damage assessments, conduct port surveillance and provide support to Navy forces at sea. Each aircraft is expected to serve for 20 years."[136]

Program Status. The Administration's FY2012 budget request documents place Milestone C for BAMS in the third quarter of FY2013, with initial operational capability in the first quarter of 2016. "Since Milestone B for the Navy BAMS UAS program, identifying opportunities for the RQ-4-based BAMS and Global-Hawk programs has been a significant interest item for the UAS TF and has been well documented within the Department."[137] In one effort to integrate development, on June 12, 2010, the Navy and Air Force concluded a Memorandum of Agreement (MOA) regarding their Global Hawk and BAMS programs, which use a common airframe. "Shared basing, maintenance, command and control, training, logistics and data exploitation are areas that could be ripe for efficiencies, says Lt. Gen David Deptula, Air Force deputy chief of staff for intelligence, surveillance and reconnaissance…. Also, a single pilot and maintenance training program is being established at Beale AFB, Calif., for both fleets."[138] However, issues still exist over common control stations and whether one service's pilots should be able to operate the other service's aircraft.

MQ-8B Fire Scout

Now in deployment, the Fire Scout was initially designed as the Navy's choice for an unmanned helicopter capable of reconnaissance, situational awareness, and precise targeting.[139] Although the Navy canceled production of the Fire Scout in 2001, Northrop Grumman's vertical take-off UAV was rejuvenated by the Army in 2003, when the Army designated the Fire Scout as the interim Class IV UAV for the future combat system. The Army's interest spurred renewed Navy funding for the MQ-8, making the Fire Scout DOD's first joint UAS helicopter.

System Characteristics and Mission. Northrop Grumman based the design of the Fire Scout on a commercial helicopter. The RQ-8B model added a four-blade rotor to reduce the aircraft's acoustic signature.[140] With a basic 127-pound payload, the Fire Scout can stay aloft for up to 9.5 hours; with the full-capacity sensor payload, endurance diminishes to roughly 6 hours. Fire Scout possesses autonomous flight capabilities. The surveillance payload consists of a laser designator and range finder, an IR camera and a multi-color EO camera, which when adjusted with specific filters could provide mine-detection capabilities.[141] Fire Scout also currently possesses line-of-sight communication data links. Initial tests of an armed Fire Scout were conducted in 2005, and the Navy expects to add "either Raytheon's Griffin or BAE's Advanced Precision Kill Weapon System" small missiles to currently deployed Fire Scouts soon.[142] Discussions of future missions

4521 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

have also covered border patrol, search and rescue operations, medical resupply, and submarine spotting operations.

Program Status. Six production MQ-8 air vehicles have been delivered to date.[143] The Pentagon's 2009 UAS Roadmap estimates a future inventory of 131 RQ-8Bs for the Navy to support the Littoral Combat Ship class of surface vessels.[144] The Army had intended to use the Fire Scout as the interim brigade-level UAV for its Future Combat System program,[145] but canceled its participation in January, 2010.[146]

A Fire Scout attracted media attention in August 2010, when it flew through Washington, DC, airspace after losing its control link. "A half-hour later, Navy spokesmen said, operators re-established control and the drone landed safely."[147]

FIRE-X/MQ-8C

The FIRE-X project, recently designated MQ-8C but continuing the Fire Scout name, is a developmental effort to adapt the Fire Scout software and navigation systems to a full-size standard helicopter. The Navy "is to award Northrop Grumman a contract to supply 28 MQ-8C Fire Scout ... to be fielded by the first quarter of 2014 to meet an urgent operational requirement."[148]

> Fire Scout can fly for 8 hours with a maximum range of 618 nautical miles? Well, Fire-X will fly for 15, with a max range of 1227. Fire Scout tops out at 100 knots? Fire-X can speed by at 140. Fire-X will carry a load of 3200 lbs. to Fire Scout's 1242. All this talk from a drone helicopter that just took its first flight in December.... Fire-X isn't going to be a big departure from Fire Scout, though. The BRITE STAR II and other radars will remain on board, as will its software for relaying information to a ship.[149]

RQ-170 Sentinel

Although publicly acknowledged to exist, most information about the Lockheed Martin RQ-170 Sentinel is classified. First photographed in the skies over Afghanistan, but also reportedly in operation from South Korea,[150] the RQ-170 is a tailless "flying wing" stealthier than other current

4522 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

U.S. UAS. An RQ-170 was reported to have performed surveillance and data relay related to the operation against Osama bin Laden's compound on May 1, 2011. The government of Iran claimed on December 2, 2011, to be in possession of an intact RQ-170 following its incursion into Iranian airspace.

System Characteristics. Built by Lockheed Martin, the RQ-170 has a wingspan of about 65 feet and is powered by a single jet engine. It appears to have two sensor bays (or satellite dish enclosures) on the upper wing surface. Although an inherently low-observable blended wing/fuselage design like the B-2, the RQ-170's conventional inlet, exhaust, and landing gear doors suggest a design not fully optimized for stealth.[151]

Potential Mission and Payload. "The RQ-170 will directly support combatant commander needs for intelligence, surveillance and reconnaissance to locate targets."[152]

Program Status. "The RQ-170 is a low observable unmanned aircraft system (UAS) being developed, tested and fielded by the Air Force."[153] No further official status is available.

Other Current UAS Programs

RQ-5A Hunter/MQ-5B Hunter II

Originally co-developed by Israel Aircraft Industries and TRW (now owned by Northrop Grumman) for a joint U.S. Army/Navy/Marine Corps short-range UAS, the Hunter system found a home as one of the Army's principal unmanned platforms. The service has deployed the RQ-5A for tactical ISR in support of numerous ground operations around the world. At one time, the Army planned to acquire 52 Hunter integrated systems of eight air vehicles apiece, but the Hunter program experienced some turbulence. The Army canceled full-rate production of the RQ-5A in 1996, but continued to use the seven systems already produced. It acquired 18 MQ-5B Hunter IIs through low-rate initial production in FY2004 and FY2005. The MQ-5B's design includes longer endurance and the capability to be outfitted with anti-tank munitions. Both variants are currently operated by the 224th Military Intelligence Battalion out of Fort Stewart, GA; by the 15th Military Intelligence Battalion out of Ft. Hood, TX; and by 1st Military Intelligence Battalion out of Hohenfels, Germany.

System Characteristics. The RQ-5A can fly at altitudes up to 15,000 feet, reach speeds of 106 knots, and spend up to 12 hours in the air. Weighing 1,600 pounds, it has an operating radius of 144 nautical miles. The MQ-5B includes an elongated wingspan of 34.3 feet up from 29.2 feet of the RQ-5A and a more powerful engine, which allows the Hunter II to stay airborne for three extra hours and to reach altitudes of 18,000 feet.[154] The Hunter system consists of eight aircraft, ground control systems and support devices, and launch/recovery equipment. In FY2004, the final year of Hunter procurement, a Hunter system cost $26.5 million.

4523 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Mission and Payload. The Army has mostly used the Hunter system for short- and medium-range surveillance and reconnaissance. More recently, however, the Army expanded the Hunter's missions, including weaponization for tactical reconnaissance/strike operations with the GBU-44/B Viper Strike precision guided munition, which can designate targets either from the munition's laser, from another aerial platform, or from a ground system. This weapon makes the Hunter the Army's first armed UAS. "Also, in 2004, the Department of Homeland Security, Customs and Border Protection Bureau, and Office of Air and Marine utilized Hunter under a trial program for border patrol duties. During this program, the Hunter flew 329 flight hours, resulting in 556 detections."[155]

Program Status. The Army halted Hunter production in 2005. As of May 2011, 45 Hunter UAVs were still in operation and periodically receiving upgrades and modifications. In August 2005, the Army awarded General Atomics' Warrior UAS (which later became Grey Eagle) the contract for the Extended Range-Multi Purpose UAS program over the Hunter II.[156]

RQ-7 Shadow

The RQ-7 Shadow found a home when the Army, after a two-decade search for a suitable system, selected AAI's close range surveillance platform for its tactical unmanned aerial vehicle (TUAV) program. Originally, the Army, in conjunction with the Navy explored several different UAVs for the TUAV program, including the now-cancelled RQ-6 Outrider system. However, in 1997, after the Navy pursued other alternatives, the Army opted for the low-cost, simple design of the RQ-7 Shadow 200. Having reached full production capacity and an IOC in 2002, the Shadow has become the primary airborne ISR tool of numerous Army units around the world and is expected to remain in service through the decade.

The Administration's FY2011 budget request did not include funding for Shadow aircraft, although it did include continued RDT&E funding for Shadow.[157]

System Characteristics. Built by AAI Corporation (now owned by Textron), the Shadow is 11 feet long with a wingspan of 13 feet. It has a range of 68 nautical miles, a distance picked to match typical Army brigade operations, and average flight duration of five hours. Although the Shadow can reach a maximum altitude of 14,000 feet, its optimum level is 8,000 feet. The Shadow is catapulted from a rail-launcher, and recovered with the aid of arresting gear. The UAS also possesses automatic takeoff and landing capabilities. The upgraded version, the RQ-7B Shadow, features a 16-inch greater wingspan and larger fuel capacity, allowing for an extra two hours of flight endurance.

Mission and Payload. The Shadow provides real-time reconnaissance, surveillance, and target acquisition information to the Army at the brigade level. A potential mission for the Shadow is the perilous job of medical resupply. The Army is considering expanding the UAS's traditional missions to include a medical role, where several crucial items such as blood, vaccines, and fluid

4524 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

infusion systems could be delivered to troops via parachute.[158] For surveillance purposes, the Shadow's 60-pound payload consists of an E-O/IR sensor turret, which produces day or night video and can relay data to a ground station in real-time via a line-of-sight data link. As part of the Army's Future Combat System plans, the Shadow will be outfitted with the Tactical Common Data Link currently in development to network the UAS with battalion commanders, ground units, and other air vehicles.[159] The Marine Corps is considering how to arm Shadow.[160]

Program Status. The Army and Marine Corps currently maintain an inventory of 364 Shadow UAVs.[161] The program cost for a Shadow UAV system—which includes four vehicles, ground control equipment, launch and recovery devices, remote video terminals, and High Mobility Multipurpose Wheeled Vehicles for transportation—reached $11.1 million in current year dollars for FY2008.[162] The Army procured 102 systems through 2009.[163] In FY2012, the Army requested $25 million for 20 Shadow aircraft to replace combat losses, and approximately $200 million for payload upgrades.

"Small UAVs"

RQ-14 Dragon Eye

AeroVironment's Dragon Eye is a backpack-carried, battery-operated UAV employed by the Marines at the company level and below for reconnaissance, surveillance, and target acquisition. Dragon Eye features a 3.8-foot rectangular wing, twin propellers, and two camera ports each capable of supporting day-light electro-optical cameras, low-light TV cameras, and infrared cameras. The compact and lightweight design of the UAV allows an operational endurance of 45 minutes and can travel as far as 2.5 nautical miles from the operator. Low-rate-initial-production of 40 aircraft began in 2001. After a 2003 operational assessment, the Marine Corps awarded AeroVironment a contract to deliver approximately 300 systems of full-rate-production Dragon Eyes.[164] However, that contract was later revised to acquire Raven UAS instead. One Dragon Eye system consists of three air vehicles and one ground station. The final Marine Corps procurement budget request in FY2006 anticipated the current unit cost per Dragon Eye system as $154,000.[165]

FQM-151 Pointer

Although procurement of this early UAS began in 1990, the electric-powered Pointer has seen service in Operation Enduring Freedom (OEF) and Operation Iraqi Freedom (OIF). Pointer is a

4525 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

short-range reconnaissance and battlefield surveillance UAV developed by AeroVironment. Its flight endurance (two hours) is greater than most similar small UAVs, in part due to its relatively large, 9-foot wingspan. That wingspan decreases portability of the 8.5-pound Pointer, and as a result, transportation of a Pointer system (two air vehicles and a ground control unit) requires two personnel. Although superseded by the Raven (below), Pointer remains a valued short-range ISR asset for the Air Force and Special Operations Command.

RQ-11 Raven

Engineered from the basic design of the Pointer, the Raven is two-thirds the size and weight of its predecessor, with a much smaller control station, making the system man-portable.[166] "The RQ-11A is essentially a down-sized FQM-151 *Pointer*, but thanks to improved technology can carry the same navigation system, control equipment, and payload."[167] The Raven provides Army and SOCOM personnel with "over-the-hill" reconnaissance, sniper spotting, and surveillance scouting of intended convoy routes. The electric motor initiates flight once hand-launched by a running start from the ground operator. The vehicle is powered by an electric battery that needs to be recharged after 90 minutes, but deployed soldiers are equipped with four auxiliary batteries that can be easily charged using the 28 volt DC outlet in a Humvee. The vehicle lands via a controlled crash in which the camera separates from the body, which is composed of Kevlar plating for extra protection. Like the Pointer, the Raven can carry either an IR or an E-O camera and transmits real-time images to its ground operators. The relatively simple system allows soldiers to be trained in-theater in a matter of days. Raven systems can either be deployed in three-aircraft or two-aircraft configurations. "Raven was adopted as the US Army's standardised short range UAV system in 2004 with a total of 2469 air vehicles (including older RQ-11A series models) in operational service by mid 2007."[168] "The US Army has an ongoing acquisition objective for about 2,200 Raven systems and has taken delivery of more than 1,300 to date."[169] A three-aircraft system costs approximately $167,000.[170]

ScanEagle

Developed by the Insitu Group (owned by Boeing) as a "launch-and-forget" UAV, the ScanEagle autonomously flies to points of interest selected by a ground operator.[171] The ScanEagle has gained notice for its long endurance capabilities and relative low cost. The gasoline-powered UAV features narrow 10 foot wings that allow the 40-pound vehicle to reach altitudes as high as 19,000 feet, distances of more than 60 nautical miles, and a flight endurance of almost 20 hours. Using an inertially stabilized camera turret carrying both electro-optical and infrared sensors, ScanEagle currently provides Marine Corps units in Iraq with force-protection ISR and is also used by Special Operations Command. ScanEagle operations began in 2004,[172] and continue

today. Although ScanEagle was expected to cost about $100,000 per copy, the Navy and SOCOM have contracted for operations instead of procurement, with Boeing providing ISR services utilizing ScanEagle under a fee-for-service arrangement.[173]

ScanEagle is also in use by non-military organizations for surveillance purposes, including tracking whale migrations.[174]

Small Tactical Unmanned Aerial System (STUAS)

In July 2010, the Department of the Navy awarded Insitu a two-year, $43.7 million contract for the design, development, integration, and test of the Small Tactical Unmanned Aircraft System (STUAS) for use by the Navy and Marine Corps to provide persistent maritime and land-based tactical reconnaissance, surveillance, and target acquisition (RSTA) data collection and dissemination. "For the USMC, STUAS will provide the Marine Expeditionary Force and subordinate commands (divisions and regiments) a dedicated ISR system capable of delivering intelligence products directly to the tactical commander in real time. For the Navy, STUAS will provide persistent RSTA support for tactical maneuver decisions and unit-level force defense/force protection for Navy ships, Marine Corps land forces, and Navy Special Warfare Units."[175]

Payloads include day/night video cameras, an infrared marker, and a laser range finder, among others. STUAS can be launched and recovered from an unimproved expeditionary/urban environment, as well as from the deck of Navy ships.[176]

STUAS uses Insitu's Integrator airframe, which uses common launch, control, and recovery equipment with ScanEagle. STUAS has a takeoff weight of up to 125 pounds with a range of 50 nautical miles. However, STUAS will be procured and operated by the services rather than operated on a fee-for-service basis because "the Scan Eagle's current fee-for-service contract limits the way the UAS is deployed ... with Boeing/Insitu employees usually operating the aircraft in the field due to liability issues." Procuring the system will allow the services to train their own operators. Initial operating capability is expected in the fourth quarter of FY2013.[177]

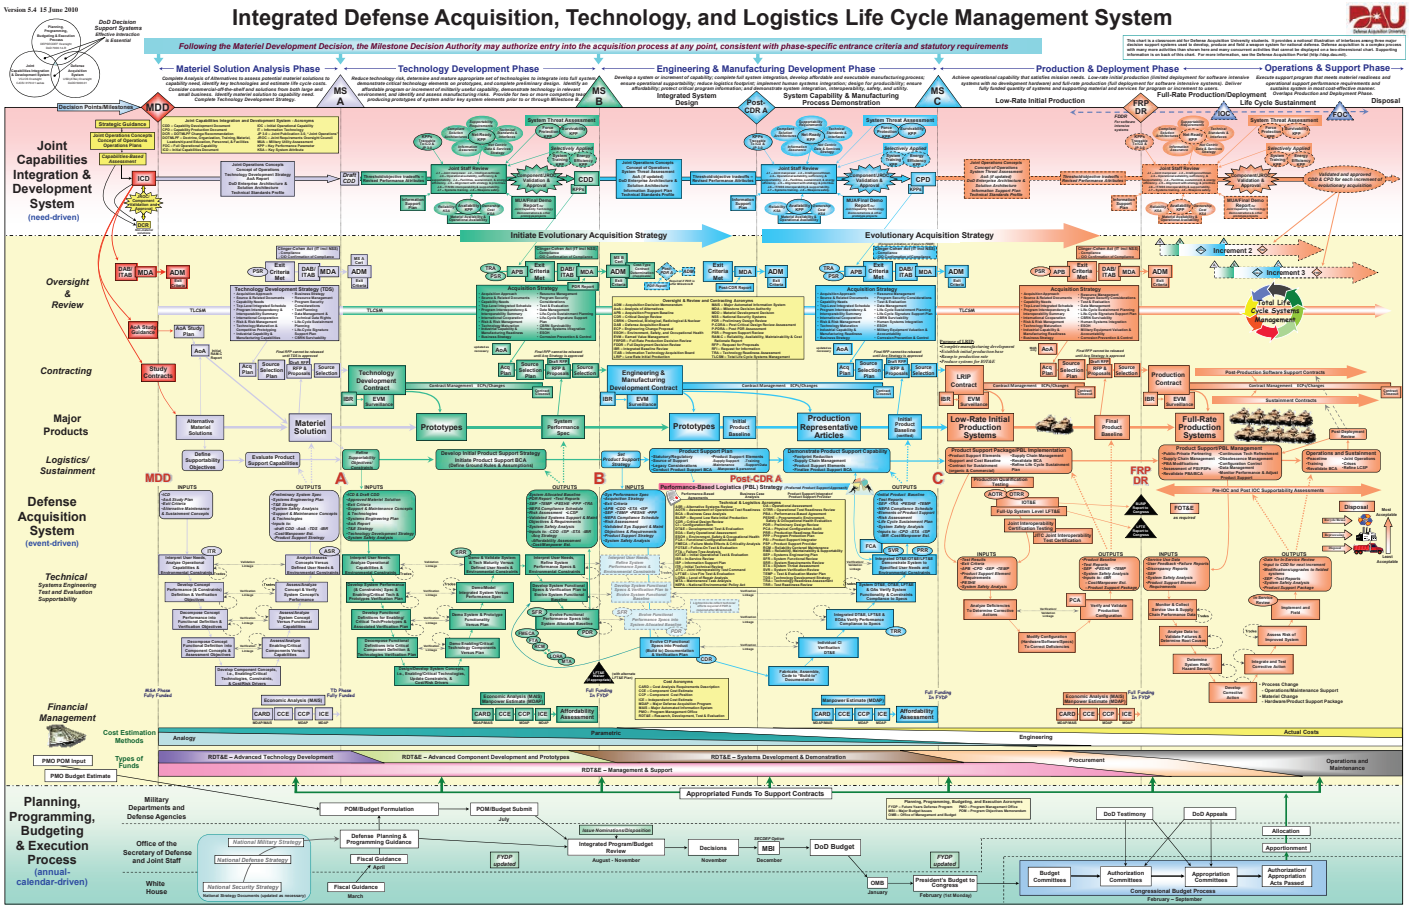
APPENDIX B

The Department of Defense's Traditional Acquisition System

Overview

The DAS is a structured and deliberate process for establishing requirements and planning and resourcing the procurement of new capabilities. The need for accountability and oversight in the allocation of national resources has led to the buildup over decades of a large bureaucratic apparatus around the DAS. The complexity of the process can be seen in Figure B.1.

This bureaucracy has many virtues. It provides for a structured process governed by regulations and accountable authorities and includes provisions for relatively stable funding over system life cycles. Such provisions are far from perfect. For example, observers have long noted that the process can be slow and unresponsive to the immediate needs of warfighters. Such concerns have led, as will be discussed below, to evolving roles for the combatant commanders in resource allocation processes. Another concern is that provision of training and sustainment considerations, while formally required, is an afterthought to the acquisition and fielding of new equipment. Both concerns will be discussed below.



Role of Combatant Commanders in Traditional Acquisition

To meet current warfighter needs, the DoD has in recent years advanced changes to some existing acquisition processes and relationships. As a result, the roles of the COCOMs in the traditional system have evolved. For example, the Secretary of Defense approved a "streamlined and refocused" integrated priority list process to better support the development of service program objective memorandums (Hicks et al., 2008, p. 59). In November 2005, the Vice Chairman of the Joint Chiefs of Staff launched a process by which the Joint Requirements Oversight Council, in consultation with the COCOMs, identified a list of "most pressing" military issues to support resourcing and planning decisions (Hicks et al., 2008, p. 59). In 2006 the Senior Warfighters Forum, consisting of COCOM deputies, began meeting every four to six weeks to discuss coordination issues, and the Vice Chairman of the Joint Chiefs of Staff began coordinating regular trips to the COCOMs with critical PPBE decision points to better represent the COCOM position in resourcing decisions (Hicks et al., 2008, p. 60). Furthermore, SOCOM's traditional acquisition activities have increased, and its budget has grown significantly (GAO, 2007b, p. 1).

The COCOMS do not lead the process, but their ability to participate in acquisition, particularly in identifying requirements, has expanded. An emphasis on warfighting in recent years has given new weight to the capabilities and solutions that the COCOMs identify as

4529 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Figure B.1
Defense Acquisition System

RAND *RR440-B.1*

4530 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

required. Beyond the current fight, however, observers argue that the nature of future challenges and the technology necessary to meet them are so dynamic that fundamental acquisition relationships need to be rethought. As the commander of SOUTHCOM recently wrote:

> We are living in an age of rapid change facilitated by advancing technologies and increasingly networked systems, societies, and economies. In order for security agencies to be successful in this complex environment, those organizations must be flexible, open and forward-thinking. (Stavridis, 2010, p. xxii)

Leadership of traditional acquisition processes is vested in the military departments (the force providers) rather than the combatant commanders (the force users). The DAS consists of the interrelationship between the establishment of requirements (Joint Capabilities Integration and Development), the process of providing solutions, and the allocation of resources (PPBE). All processes are primarily driven by the military departments, with some inputs from the COCOMs. The logic behind the vesting of acquisition authority in the military departments reflects both Title 10 responsibilities and unique competencies for acquisition. The division of labor has traditionally been that the COCOMs provide inputs to the determination of requirements, and the services lead on providing solutions. A recent RAND assessment concluded that it "is the job of those in Washington, D.C., to reach out to the COCOMs and demonstrate that their needs are being addressed, rather than turn the process over to them" (Blickstein and Nemfakos, 2009, p. 7). Traditionally, the COCOMs are viewed as best suited to fighting wars, while the military departments are best suited to balancing other priorities and managing resource decisionmaking.

APPENDIX C

Military Value Analysis of Unmanned Aircraft System Training Bases

Training Locations

The information on specific training locations included in this appendix is drawn from RAND interviews, service presentations to congressional oversight committees, and Army surveys and consolidated snapshots of selected Army bases compiled in November 2012.

Initial training for UAS operators and sensor operators is concentrated at a few locations. The Air Force uses Beale AFB for training its Global Hawk crews and primarily Holloman AFB for its Predator crews.[1] The Navy plans to leverage the similarities between the Global Hawk and BAMS by having some joint training at Beale AFB. The Army conducts all its initial UAS training at Fort Huachuca, Arizona. The Marine Corps trains its Shadow crews with the Army.[2] Current and continuing pressures on the defense budget are likely to result in further changes. We limited our efforts to analyze military value in depth to activities that any training base would more certainly include, regardless of budget reductions. After we gain a fuller understanding of the results of Secretary of Defense decisions on the content of the FY 2014 and FY 2015 programs, we will renew our efforts to complete this military value analysis.

The approach to the *military value analysis of training bases* presented here is based on the Department of the Navy's 1995 Base Realignment and Closure documents. These categories and a brief description are listed below:

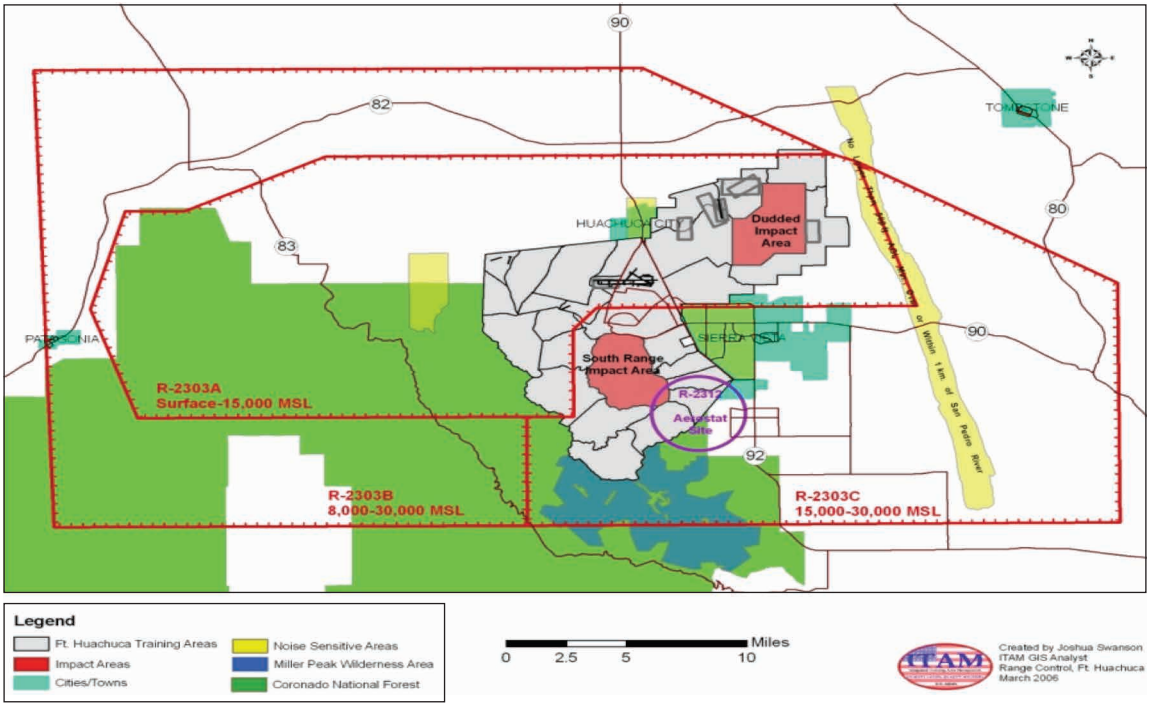
- flight training areas and airspace—covers access to special use airspace, availability of training areas, etc.
- airfield and maintenance facilities—includes facilities available for housing and maintaining the aircraft
- expansion potential—any comments on future plans for expansion or capacity for expansion
- training and training facilities—includes classrooms or other similar infrastructure and equipment required for training
- military and general support mission—any impacts of the other military missions housed at the same installation

[1] The training for the LRE is separate from the FTU and takes place at Creech AFB, Nevada.

[2] The Marines will also operate the RQ-20A Puma. We do not discuss the training for that SUAS.

4533 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

- weather—any impacts of weather on training capacity
- location—description of the where the installation is located
- base loading—comments on consolidation of training.



Army RQ-7 and MQ-1C Training IQT Fort Huachuca, Arizona

Fort Huachuca, Arizona, is home to the 2-13th Aviation Regiment (formally the Unmanned Aircraft Systems Training Battalion). The 2-13th trains operators and maintainers for the RQ-7 Shadow, the Warrior Alpha, and the MQ-1C Gray Eagle. The training pipeline for each of these was described in the body of this report.

Flight Training Areas and Airspace

See Figure C.1. R-2303 is a major operational area used for airspace manned and unmanned operations, Army and joint service training along with Department of Homeland Security border security operations. Fort Huachuca is the controlling authority and so can activate this restricted use airspace on demand, at any time. It covers 850 mi^2 of land outside Fort Huachuca and encompasses 4,600 mi^3 of airspace from the surface to 30,000 feet, much of it over private land. The FAA has issued several waivers to ensure the safe operations of manned and unmanned traffic. The area also has unencumbered radio frequency spectrum for the foreseeable future.

Figure C.1
Airspace Surrounding Fort Huachuca

RAND *RR440-C.1*

4534 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Airfield and Maintenance Facilities

See Figure C.2. UAS operations split between the Libby Army Airfield and Black Tower. Shadow and Hunter training takes place at Black Tower. There are dedicated maintenance facilities as well as hangers and airstrips. Gray Eagle training takes place at Libby Army Airfield.

Expansion Potential

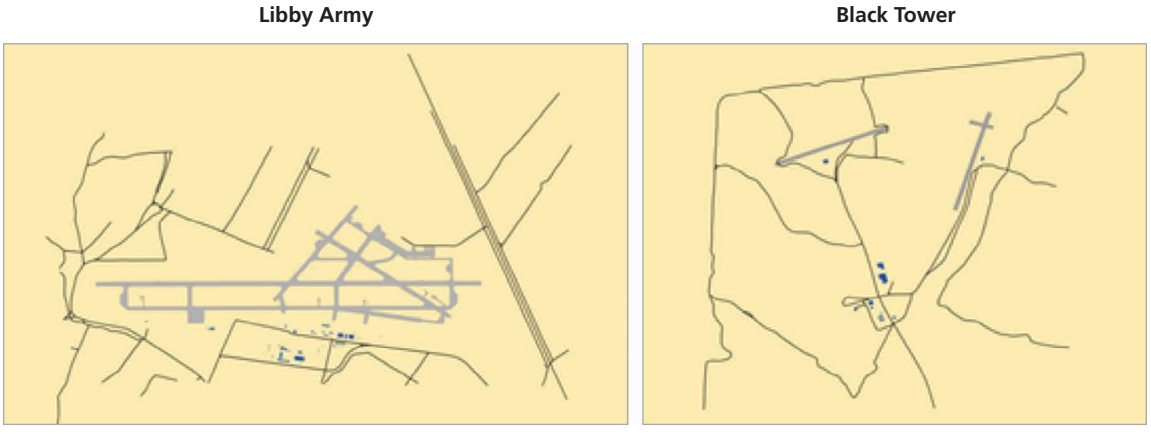
The IQT common core and the course for Shadow are currently running 24-hour operations. It would be difficult to expand the student capacity without committing more resources. The Gray Eagle course is just beginning, and the Hunter course is winding down. There is enough infrastructure for the planned capacity. Any expansion would require more resources.

Training and Training Facilities

Most UAS training operations take place at the Black Tower complex. Gray Eagle and Warrior Alpha vehicles are flown out of Libby Army Airfield.

Military and General Support Mission

Fort Huachuca is home to the military intelligence schoolhouse. This proximity could provide a unique opportunity for collective training between the two schoolhouses. Huachuca is also home to the Buffalo Soldier Electronic Testing Range.



Weather

Fort Huachuca has excellent weather for UAS operations. It has approximately 270 training days a year.

Location

See Figure C.3. Fort Huachuca is situated in southeastern Arizona, near the town of Sierra Vista. There are approximately 60,000 people at Fort Huachuca.

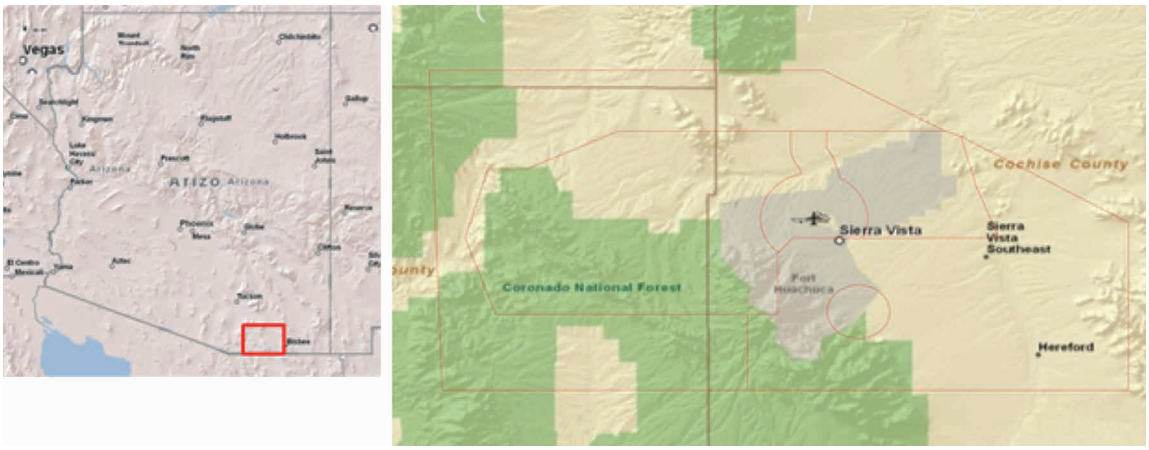


Figure C.2
Airfield and Maintenance Facilities at Fort Huachuca

RAND *RR440-C.2*

4535 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

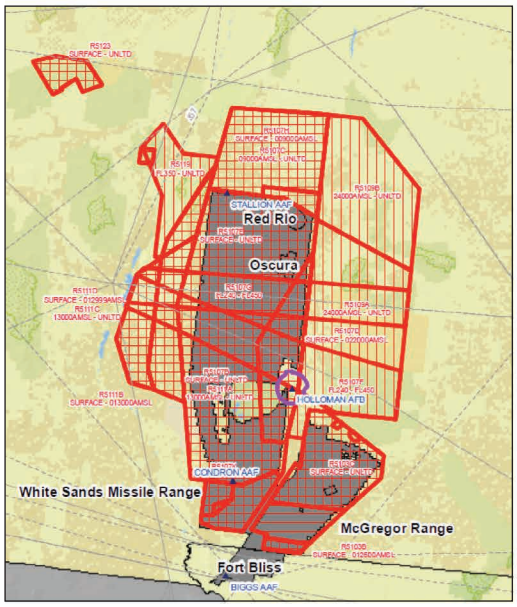
Figure C.3
Location of Fort Huachuca

RAND *RR440-C.3*

Base Loading

Fort Huachuca is the hub for Army UAS training. This consolidation could be both good and bad. The lack of redundancy elsewhere limits the ability to expand operations when needed. For example, if one of the runways were damaged, the entire Army UAS training capability could be severely affected.

Air Force Active Duty MQ-1/9 Formal Training Unit—Holloman AFB, New Mexico



Flight Training Areas and Airspace

See Figure C.4. Holloman AFB has access to the restricted airspace areas within the White Sands Missile Range (WSMR) and McGregor airspace. It is possible to reach both ranges without leaving restricted airspace. While competition for airspace is fierce, WSMR supports flying RPA operations out of Holloman AFB. The current plan is for MQ1/MQ9 to depart Holloman AFB northbound for WSMR airspace and to remain totally within R-5107 B/C/D/H. An alternative is to depart Holloman AFB southbound and climb to FL-180 in R-5107D. There is a three-way memorandum of understanding in place, but the testing mission at WSMR occasionally conflicts with RPA training. A few other areas near Holloman AFB have potential for RPA operations, although they require COAs from the FAA.

The MQ-1/9 FTU completed the transition from Creech AFB to Holloman AFB. Plans call for an additional FTU, bringing a total of five MQ-1/9 training squadrons, including one maintenance squadron, to Holloman AFB. These squadrons will fall under the 49th Wing and bring in an additional 200 officers, 250 enlisted, and 150 contractors. Two hundred students are expected to cycle through in three-month training periods. Holloman AFB would have 28 MQ-1s and 10 MQ-9s. To operate the aircraft, they would have 12 common ground stations, four Predator Primary Satellite Links, two LREs, and five mission control elements. They expect to fly approximately 2,800 sorties a year, 540 at night.

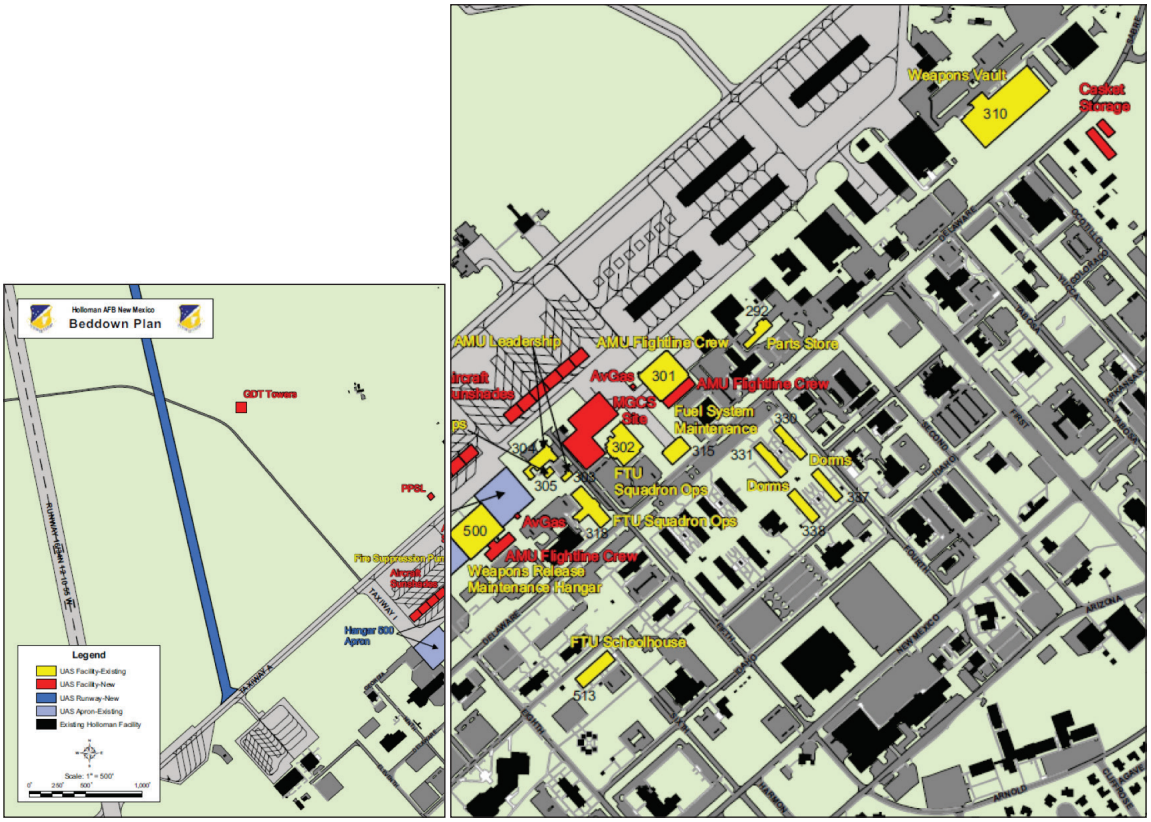
RAND *RR440-C.4*

Airfield and Maintenance Facilities

These are included with the training facilities.

Expansion Potential

The second MQ-9 FTU is scheduled to open in FY 2013, making Holloman home to three MQ-1/MQ-9 FTUs. There is currently a year lag in infrastructure to be able to support a third FTU. The new facilities were supposed to have been finished prior to the standup of the new FTU; however, construction is running approximately a year behind schedule. It is difficult to comment on the ability to meet the required capacity as the capacity requirement is in flux.



Training and Training Facilities

See Figure C.5. Holloman AFB has 200,000 ft^2 of existing and open facilities, including office space and hangars that could accommodate the FTUs with minor renovations. The map in Figure C.5 shows where new facilities would be located and identifies existing facilities.

Table C.1 shows the space required to start up the unit, as well as the required final bed-down space, as defined by military construction. Table C.2 shows the facility plan for each functional requirement.

4537 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Figure C.5
MQ-1/MQ-9 Beddown Plan

RAND *RR440-C.5*

Military and General Support Mission

Other aircraft flown at Holloman currently include the T-38, MQ-1, MQ-9, the QF-4, and the German Tornado.[3] There are plans to move at least a portion of the F-16 FTUs from Luke AFB, Arizona, to Holloman AFB. This could affect the availability of airspace access.

Location

Holloman AFB is located in southern New Mexico, near the town of Alamogordo. The base encompasses about 59,600 acres and has a population of about 21,000 military, civilian, and families.

Base Loading

Moving the FTUs from Creech AFB to Holloman AFB freed up some capacity at the former and allowed the latter to focus purely on training.[4] There is some redundancy with the Air National Guard FTU at March ARB; however, that FTU is much smaller and primarily trains

[3] A German training unit is stationed at Holloman AFB. The F-22s will be transitioning from the base. Air Combat Command and the Air Staff are deciding what to put in place of the F-22 squadron.

[4] The LRE training is a separate course from the FTU and still taught at Creech.

[a] Use maintenance bay.

Air National Guard operators. March ARB currently has adequate infrastructure and capacity for its training mission.

Air Force RQ-4 Formal Training Unit—Beale AFB, California

Flight Training Areas and Airspace

Because of the altitude at which RQ-4s conduct their primary mission, airspace access is manageable at Beale AFB. A cylinder is used to access Class A airspace. The FAA provides a standing window for flights into this cylinder of 10 hours a day, every weekday. Requests outside this window are handled individually and have not been a limitation.

Airfield and Maintenance Facilities

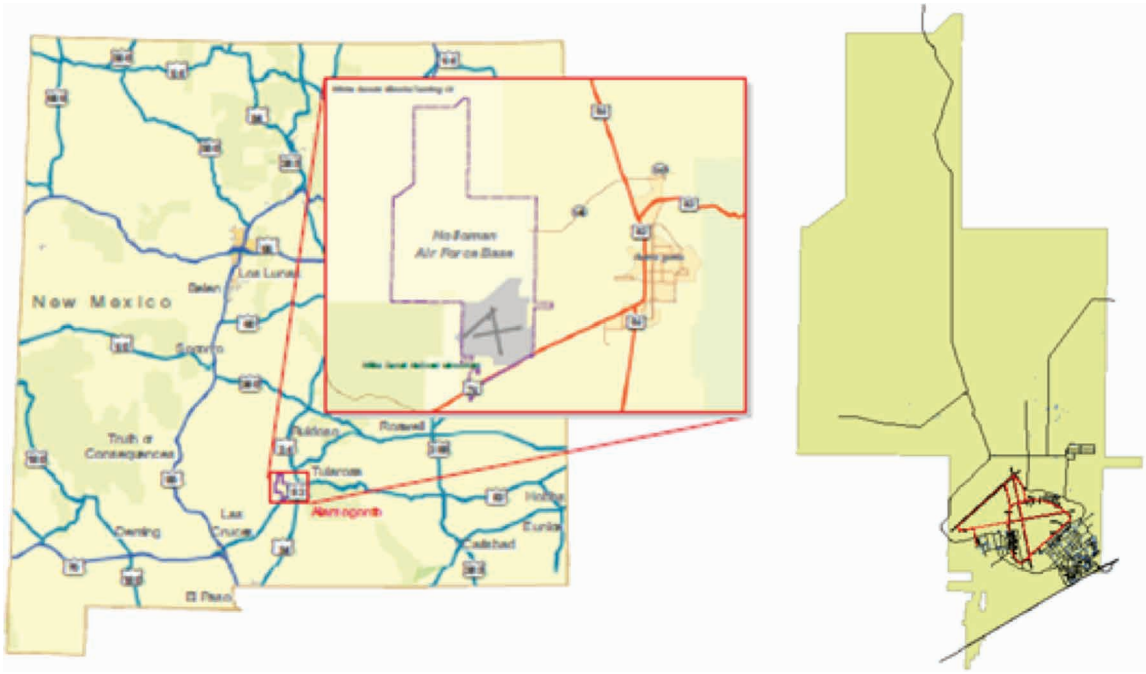
Beale AFB has dedicated airfield and maintenance facilities.

Expansion Potential

There is enough capacity for expanding the training mission of RQ-4s at Beale AFB. There are plans to include some portion of the operator or maintenance training for the Navy's MQ-4 BAMS at Beale, but this would be several years from now.

4539 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Table C.2
Facility Requirements



Function Description	Remarks
Flightline pavement	Use main ramp.
Live ordnance load area	Construct new LOLA on taxiway Echo.
Maintenance hangar (new FTU)	Use building 500.
Maintenance hangar (3 FTU squadrons)	Use building 301.
FTU squadron operations (new FTU)	For initial capability, use building 513 and a portion of building 302; when project is complete, transition from building 513 into building 318.
FTU squadron operations (Creech UAS)	If there are two FTU squadrons, use building 318; a third FTY squadron can occupy all of building 302 after F-22A transition is complete.
Aircraft maintenance unit (new FTU)	Initially locate leadership team in building 303 and operate flightline crews out of building 301 until completion of building 500 new construction (10,000 ft^2).
Aircraft maintenance unit (3 FTU squadrons)	If two units, locate both leadership teams in building 303 and flightline crews of the second unit in building 301. If three units, locate third leadership team in building 302 and locate flightline crew in building 302. New construction for building 301 can also be considered for the third crew.
Fuel system maintenance	Use building 315.
Precision guided munitions facility	Construct two maintenance bays and administration.
Munitions storage	Construct 26-by-120-ft Hayman igloo (possibly two 60-ft sections).
Aircraft parts store (new FTU)	Use existing contract support or shared building 292 (T-38 parts store).
Aircraft parts store (3 FTU squadrons)	If T-38 mission relocates, use building 292. If no relocation, add space to building 292.
Weapon release shop	Use each respective maintenance bay (building 500 for one and building 302 for two).
Casket storage	Construct 50-by-800-ft covered storage pad in logistics readiness squadron yard. Requirement may grow, depending on quantity of MQ-9 caskets on hand.
Bulk fuel storage	Construct two 8,000-gallon tanks adjacent to hangars 301 and 500 (for aviation gas) for MQ-1 and use existing JP-8 capacity for MQ-9.
Various backshops	Construct 5,000-ft^2 addition on building 500. Building 301 may require new additional space.

Training and Training Facilities

Beale AFB has adequate training space. There are several different aspects of training: classroom, simulation, and live flights. There is enough classroom space available for both the sensor operator training and the pilot training. The pilots use a pilot simulator to cover emergency procedures and aircraft operation. This simulator is very limited in its ability to mimic real-life contingencies. The sensor operators train on Data Analysis Workstations. These two simulators are not compatible, so there is no true crew simulator. Such a simulator has been

4540 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Figure C.6
Location of Holloman AFB

RAND *RR440-C.6*

programmed but is still eight to ten years away.[5] Crew training takes place on live missions, with instructors flying the mission with students.

Military and General Support Mission

Beale AFB is home to several other aircraft, including the MC-12, the U-2, and the T-38. The RQ-4 fits well with the mission of other aircraft at Beale since it was designed to eventually replace the U-2. RQ-4 pilots are also doing tours in the MC-12. There was some talk of maintaining dual currency in the two platforms, but the status of that plan is unknown.

Location

Beale AFB is located in northern California, approximately one hour outside Sacramento. The nearest town is Marysville, California.

Base Loading

Beale AFB is the hub for high-altitude surveillance. The installation is extremely large, with plenty of room for growth.

[5] We understand this decision to be based on resources since on-the-job training on live missions is available.

4546 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Unmanned aircraft systems (UASs) have become increasingly prevalent in and important to U.S. military operations. Initially serving only as reconnaissance or intelligence platforms, they now carry out such other missions as attacking enemy forces. The swift expansion in their numbers and in the demand for their employment has, however, significantly increased demands on logistics and training systems. The challenge is not simply training system operators but also training operational forces and their commanders to integrate the systems into combat operations. Much of that aspect of training has thus far happened as units employ the systems in actual operations—essentially, on-the-job training. UAS training, particularly for the employment of UASs, now needs to be integrated more formally and cost-effectively into service and joint training programs. This report develops a general concept for training military forces in employment of UASs and a framework for addressing the training requirements and discusses the limits of existing infrastructure in supporting UAS training. Interoperability among services is another issue, because services have thus far mainly developed training suitable for their own needs. But the services have established a set of multiservice tactics, techniques, and procedures for UASs, which should facilitate interoperability training. At present, units are not always ready for joint training, so the focus should be on improving training at the unit level in the employment of UAS capabilities, with the overall guiding principle being to "train as we fight."

4553 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Preface

During the most recent rounds of Base Closure and Realignment Commission activities in 2005, a significant number of training bases were closed. In light of the introduction of new technologies and the great expansion of unmanned aircraft systems (UASs) in the force, Department of Defense planners and some in Congress have become concerned that the existing training infrastructure—bases and their training support facilities—may not be adequate to train UAS air and ground components and the ground forces that use such equipment to capitalize fully on their capabilities. Accordingly, the Deputy Director, Readiness and Training Policy and Programs in the Office of the Under Secretary of Defense for Personnel and Readiness (OUSD [P&R]) asked the RAND Corporation to assess the adequacy of UAS training to support current and future requirements. In addition, the House Armed Services Committee report accompanying the Fiscal Year 2013 National Defense Appropriations Act raised a number of questions concerning training strategies with particular reference to the use of simulators to facilitate training.[1]

This report considers three issues: (1) the development of a general concept for UAS training in the context of current and anticipated future UAS inventories, (2) the development of an appropriate framework based on the general concept to address UAS training requirements, including the appropriate use of simulators, and (3) the airspace requirements necessary for UAS training. The research reported on here covers UASs in the Army, Navy, Air Force, and Marine Corps as fielded and plans as they existed during 2012. A RAND team carried out extensive field visits to understand the current ability of the services to conduct (1) service-specific training and (2) joint training at both home station and joint training facilities. The research will be of interest to those concerned with UAS programs and operations; joint training; or more generally, the incorporation of disruptive technologies into Department of Defense programs and operations.

This research was sponsored by the OUSD (P&R) Directorate for Training and Readiness Policy and Programs, in coordination with the Joint Forces Command's Joint Warfighting Center and the Joint Unmanned Aircraft Systems Center of Excellence. The research was conducted within the Forces and Resources Policy Center of the RAND National Defense Research Institute (NDRI), a federally funded research and development center sponsored by the Office of the Secretary of Defense, the Joint Staff, the Unified Combatant Commands, the Navy, the Marine Corps, the defense agencies, and the Defense Intelligence Community. 4558 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Summary

Unmanned aircraft systems (UASs) have become increasingly prevalent in and important to U.S. military operations. The number of systems has surged, as has the slice of the defense budget allocated to them. Roles have also changed. Initially employed only as reconnaissance or intelligence platforms, they now carry out other missions, including attacking enemy forces. Successful operational tests and demonstrations of the expanded range of UAS capabilities have led to rapid fielding of new systems, often placing unanticipated demands on logistics and training systems and on field commanders to employ new systems effectively. UASs must now be integrated into the training programs of the services. Building a responsive, effective, and efficient UAS training program is a challenge during times of reduced budgets. Any new program must be based on a review of existing training capabilities and new investments across the services.

Focus of this Research

The Deputy Director, Readiness and Training Policy and Programs, in the Office of the Under Secretary of Defense for Personnel and Readiness (OUSD [P&R]) asked the RAND National Defense Research Institute (NDRI) to assess the adequacy of UAS training to support current and future requirements. Proposals to resolve service and joint UAS training issues must be informed by a clear understanding of current problems, opportunities for correction, and associated costs and benefits of the corrections. In this report, we address a number of issues, including (1) a general concept for UAS training; (2) an appropriate framework to address UAS training requirements, including the use of simulators; and (3) the limitations of the infrastructure to accommodate UAS training, including those due to national airspace restrictions. The research considers UASs in the Army, Navy, Air Force, and Marine Corps, both those that are currently fielded and those that were planned to be fielded as of 2012.

Disruptive Technologies and Acquisition Processes

In 1995, Clayton Christensen introduced the term *disruptive technology*, distinguishing it from what he termed *sustaining technology*. In his nomenclature, a sustaining technology improves the performance of an existing system and does not require significant structural adjustments to processes, organizations, or operational paradigms. Disruptive technologies, however, change the way a business operates. The UAS is a disruptive technology.

4560 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

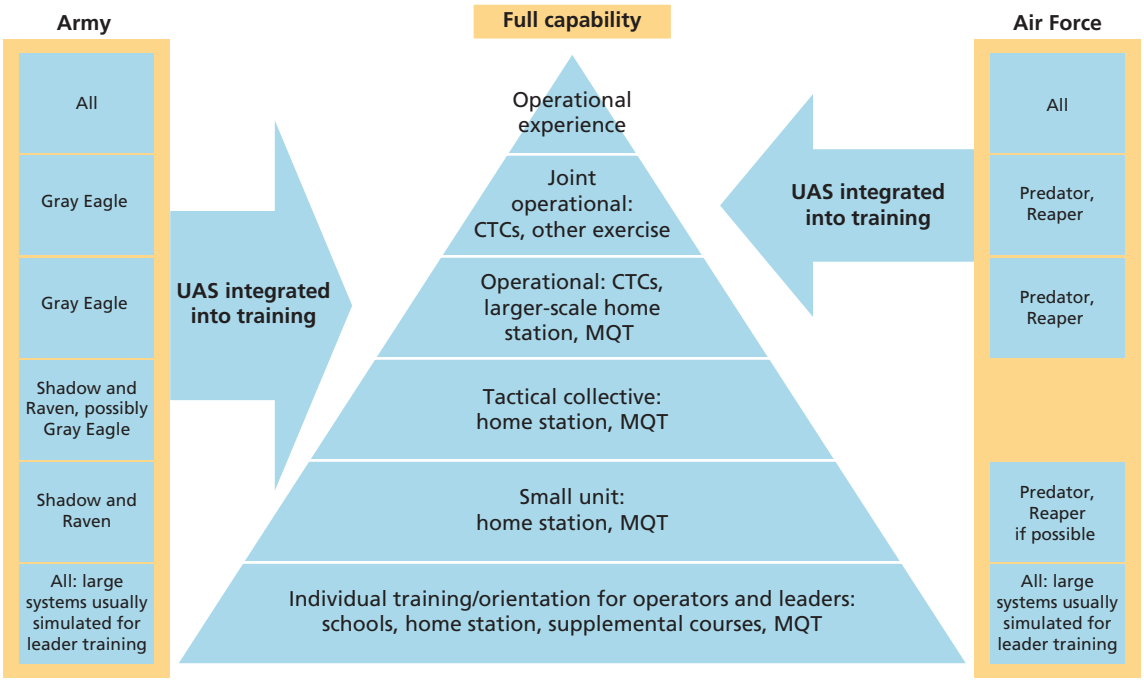
UASs found their way into the force by means of rapid acquisition procedures that were designed to deliver new technologies to the warfighter much faster than traditional procedures could, but often at the cost of not having in place the support these new systems required to become a sustained part of the force structure. Because of the rapid acquisition of these systems, the services have had to rely upon contractor support in ways that are inconsistent with the full and sustaining integration of these systems into service inventories. Such integration starts with the development of an appropriate concept for training.

Training Concepts and Frameworks

We will begin by discussing the general ideas that should guide UAS training—the training *concept*. Then, we will consider how the parts identified in the concept fit together into a conceptual structure for that training—a training *framework* designed to enhance combat power and other operational capabilities.

Joint Operations; Multiservice Tactics, Techniques, and Procedures; and UAS Training

Military operations today are usually referred to as *joint operations*, emphasizing the interdependence of the services. That might lead one to think that joint doctrine; joint concepts of operation; and joint tactics, techniques, and procedures would provide focus for training. Clearly, training does not take place for its own sake; it should be driven by doctrine. In his cover letter to Joint Publication 3-0, 2011, ADM Mike Mullen stated that it established "the framework for our forces' ability to fight as a joint team," but nowhere does it discuss the management of UASs. Moreover, nowhere in any other joint publication is there a grand doctrine for the employment or management of UASs on the battlefield. While the services have agreed to a set of multiservice tactics, techniques, and procedures (MTTPs) to be incorporated into their respective training programs, note the use of *multiservice* rather than *joint*.



At least for the foreseeable future, each service will continue to field UASs and must bring to the fight forces fully capable of operating them and integrating their capabilities into operations. While grand doctrinal issues remain unresolved, common procedures agreed to and trained by the services will remain the foundation on which American military operations must be built. In this way, rather than being the foundation for UAS training, joint operations are the goal of such training, which must be firmly grounded on the UAS training each service gives both its supported and supporting units.

The general concept we advance for UAS training here rests on the notion that the greatest beneficial effect—that is, an increase in the force's operational effectiveness—occurs with a synergy among the UAS platforms, those who operate them, and those who integrate them into combat operations. While the report considers training concepts for ground, air, and sea forces, they share a common framework. Figure S.1 depicts our framework for ground and air forces; the one for naval forces is similar.

The concept underpinning the framework calls for increasing integration of its several parts as the level of training moves up the pyramid. Army systems appear on the left, Air Force on the right. At the bottom, training begins with individual training for operators and leaders, grounding each group in the basics of the system. Training then progresses to the small unit level, which, as with individual training, is largely done at home station. Moving up the pyramid, training occurs at increasingly higher echelons, battalion and brigade. Moving to joint

Figure S.1
UAS Training Framework

RAND *RR440-S.1*

operations involves Air Force units, which have gone through a similar process of progressive training. They join together in exercises, many of which are conducted at the large combat training centers (CTCs), to integrate close air support and Air Force UASs into the ground maneuver plan.

Assessment of the State of UAS Training in 2012: Service and Interoperability Training and the Role of Simulators

Service Training

Speaking generally, the services have been relatively effective at training the individual skills required to operate and maintain the UASs, although the services differ in their approaches. The Army, which tends to use enlisted personnel to staff its UAS units, has developed courses that award Military Occupational Specialties for the operators and maintainers for its Shadow and Gray Eagle systems. Training for the Raven UAS, which is about the size of a large model airplane and is used to support lower-echelon units, is a unit responsibility carried out through a "train-the-trainer" concept. The Marines use officers who are qualified aviators or aviation command and control officers as pilots, and enlisted personnel operate the payloads. The Air Force pilots are officers and are either rated pilots who graduated from pilot training or UAS-only pilots who graduated from a program designed specifically for flying UASs. Sensor operators for Reaper and Predator are either trained into a new career field or cross-trained from another Air Force Specialty Code. Those for Global Hawk come from the imagery analyst

4562 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

career field. Maintenance personnel come through the Air Force's maintenance education and training programs.

The more challenging part of the training comes at the integration level, where UAS personnel must meld their efforts with those of ground combat units. This occurs within and between services. Integration requires substantial practice under realistic conditions that do not occur frequently. Rotations at a CTC are often the only occasions, short of actual operations in theater, in which commanders face the challenge of integrating all battlefield operating systems at once, and the addition of the UASs necessarily complicates synchronization and integration tasks. Thus, it is not surprising that initial assessments of UASs during integrated training are, at best, mixed.

The key concerns of UAS units tend to be similar across services. For ground and Air Force units, the concerns are beddown and support facilities, airspace limitations, and simulators. Many of the beddown and support issues can be resolved with relatively minor construction. Some airspace issues, however, are not likely to improve. The Navy has airspace issues at specific installations but generally faces fewer restrictions because it can operate outside the 12-mile coastal limit with relative freedom.

Interoperability Training

To date, interoperability training at the National Training Center (NTC) and the Joint Readiness Training Center has been limited. The Government Accountability Office (GAO) has cited two significant challenges for improved interoperability training: (1) "establishing effective partnerships with program stakeholders through comprehensive communication and coordination and (2) developing joint training requirements that meet combatant commanders' needs," with particular emphasis on tactical-level training (GAO, 2005, p. 2).[1] To meet this challenge, the Department of Defense (DoD) established an implementation plan that gives the Office of the Under Secretary of Defense for Personnel and Readiness overall responsibility and the Deputy Under Secretary of Defense for Readiness executive agent responsibility for training transformation planning, programming, budgeting, and execution progress.[2]

While RAND did not assess interoperability training in detail, our discussions with the training community, including trainers at the NTC, suggest that such training opportunities have been limited because Air Force assets, particularly the Predator, have generally been unavailable due to pressing operational requirements in Iraq and Afghanistan. This same general observation was also reported by the GAO (2010b, p. 26). The problem of transiting Air Force UASs from Creech Air Force Base, Nevada, to the NTC at Fort Irwin, California, through Federal Aviation Administration–controlled airspace is often cited. Permanently stationing Air Force UAVs at the NTC, much as the Marine Corps has done by stationing Shadow UAS squadrons at the Marine Corps Air Ground Combat Center at Twentynine Palms, California, to support training there, would of course negate that problem. However, the experience of the Marine Corps suggests that the mere presence of UASs will not ensure

---

[1] GAO, 2005, p. 18, noted that,

> [i]n the past, joint training tasks were primarily focused at the command level and were identified through DOD's authoritative processes that built requirements by translating combatant commander inputs into training requirements. Training transformation has expanded joint training requirements to include those at the tactical level in addition to joint command-level training.

[2] See Director, Readiness and Training Policy and Programs, 2006.

4563 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

that the forces are properly trained. The forces must be prepared for such training at their home stations. In addition, given the common MTTP, forces trained to operate with their own service UASs should find working with UASs from the other services less challenging.

Simulators

Congress has pressed for information on the role simulators might play in a UAS training strategy, seeking an "informed balance between live training and simulated training."[3] But the conditions that make a compelling case for using simulators in the training of fighter pilots are largely absent when it comes to UAS training:

1. UAS flying hours are much less expensive than flying hours for manned aircraft.
2. The kinds of operational activities that need more training emphasis, in particular air-ground coordination, are generally not activities for which simulators per se can substitute for live flying.
3. While simulators are an inherent part of the systems used for initial training of pilots and sensor operators,[4] they are not well suited (and not designed) for training operating forces on the full spectrum of UAS capabilities.
4. At best, simulators complement rather than substitute for live training. Given the current state of the fielding of UAS, first priority must be given to building the live flying infrastructure. Then, and only then, might funds be used to undertake the research and development that must precede any consideration of fielding the kind of interactive UAS air-ground simulators that could train both UAS crews and ground troops.

We concluded that, given current budget limitations and the importance of fully developing the opportunities for live training and the relatively low cost of such training, diverting funds to develop higher fidelity UAS-ground simulators would be unwise at this time. However, the Army's air-ground integration ranges provide a good example of judicious use of simulators to do what simulators do best—in this case, scoring target hits without using expensive live munitions and without blowing up fairly expensive targets. In the future, the services should reevaluate the need for virtual training based on a cost and effectiveness analysis (COEA) that includes developmental costs for simulators, savings based on the costs of flying UASs, and the critical availability of air space for training.

Implications and Recommendations

The Guiding Principle: "Train As We Fight"

DoD has been under some pressure from the Congress and such organizations as the General Accountability Office for the lack of central control and the lack of the development of joint DoD strategy for training. In reality, the services continue to develop UAS training initiatives primarily to meet their own unique requirements, and the opportunity for joint training is limited. Progress has, however, been made with the development of the MTTP and the recognition that interoperability training is a service responsibility. For now, DoD should encourage

[3] See, for example, Chairman, House Armed Services Committee, undated.

[4] See Shawn Johnson, UAS cost per flying hours, personal communication, April 10, 2013.

4564 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

each service to solve its own UAS training problems, not constrain any one service under the guise of joint training. Given strong service programs, there will be ample opportunity to focus on joint training in the future, when the opportunity presents itself. Today, however, the services are still struggling with how to incorporate these new systems. The appropriate strategy for UAS training is to insist that the services train as they will fight. Accordingly, to *train as we fight* in the future, DoD training strategy must

- engender better appreciation of UAS capabilities throughout the chain of command
- address organizational, structural, and infrastructure and support issues
- enable "train as we fight" in collective unit training
- enable "train as we fight" in exercises.

Initiatives with Near-Term Payoff

To accomplish these goals, a number of initiatives should pay off in the near term, including

1. increasing exposure to the capabilities and limitations of UASs
2. harnessing the lessons-learned process to guide the development of service and joint doctrine and tactics, techniques, and procedures
3. addressing well-known but underresourced training infrastructure shortfalls.

Institutionalize Training for UAS Capabilities Over the Longer Term

Institutionalization will require more-general efforts, including

1. acculturation (Many end users do not yet have a well-developed appreciation of UAS capabilities.)
2. development of a cadre of UAS professionals with hands-on experience in all echelons of UAS operation
3. integration of UASs into service force structures
4. adaptation, including
   a. accounting for the evolution of the roles of UASs in the full range of military operations
   b. continuous resolution of UAS doctrinal issues.

Summary of Findings and Recommendations

The findings and recommendations are summarized below:

1. The proper strategy for DoD at this time is to encourage each service to solve its own UAS training problems, rather than to constrain any one of them under the guise of joint operations.
2. DoD should support current and future programs to develop ranges and beddown and support facilities similar to those in the Army's current programs.
3. In spite of the demands of deploying units and sustaining combat operations in Afghanistan, Army trainers indicate that Army units are better at maintaining qualification for Shadows than for Ravens. Nevertheless, not all units have been able to maintain high

4565 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Shadow qualification rates—some units arrive at the NTC with one-half or fewer of their operators qualified.

4. If joint training becomes a priority, the Air Force's current basing and beddown posture will become a problem. The Air Force could consider the location of Army hubs when choosing where to base its UAS fleet. A location that is near Army maneuver elements might make airspace access less of a restriction or at least make certificates of authorization more practical. Proximity might provide more opportunities for training UAS integration throughout the entire mission planning process.
5. Given current budget limitations and the importance of fully developing the opportunities for live training and the relatively low cost of such training, diverting funds to a research and development program to develop higher-fidelity simulators would seem to be unwise at this time.

Path to the Future

This report presents and discusses a multitude of means for setting up UAS training strategies for success, including supporting ongoing facilities and basing initiatives; expanding such facilities, where possible, to enable wider availability of UASs to support collective training; and increasing the use of UASs—the complete UAS package, including joint tactical air controllers and other coordinating elements—in collective training, both local and in larger exercises. We have noted the need to support continuing efforts to resolve airspace access issues, observing as we did so that there are ways to keep such restrictions from imposing serious limitations on much of the UAS training envisioned here. Similarly, we have discussed the potential for simulators to add value in training, now and perhaps more in the future. But we have also cautioned that simulators in their current state are not a good substitute for live use of UASs in collective training.

The path to the future for UAS strategies starts now, with support for ongoing initiatives that will continue the trends toward better training integration, thus improving the ability of end users to employ the multiple capabilities of UASs in their operations. The path continues, using that foundation, with longer-term efforts to add to acculturation of end users, professionalization of the UAS community, and integration of the two to harmonize the capabilities of UASs as key elements of overall force effectiveness.

Acknowledgments

The research presented here is the result of numerous field visits and discussions with members of service and department staffs in the Pentagon, commanders and operations staffs in operational arms of all the services, planners and training developers in service training commands, trainers and staffs at the various combat training centers, students in UAS operator schools, and UAS operators. So many shared information and data and providing thoughtful comments, advice, and insights that it is impossible to single out anyone without possibly slighting someone else. Moreover, the views expressed in this report are our own and should not be attributed to any individual or organization.

We would be remiss, however, if we did not recognize the support we received from Frank DiGiovanni, Director of Training Readiness and Strategy in the Office of the Under Secretary of Defense (Personnel and Readiness), and Joan Vandervort, our project coordinator in Mr. DiGiovanni's Office. Their commitment to developing an appropriate training strategy for UASs was the driving force behind this study.

CHAPTER ONE

Introduction

UASs Play an Increasing Role on the Battlefield

During the last decade, in large part because of the dynamic nature of operations during Operation Enduring Freedom and Operation Iraqi Freedom, recognition of the importance of developing new capabilities to meet the ever-changing threats our military forces face has grown. As a result, the Department of Defense (DoD) has undertaken operational and technology demonstration projects to test new technologies and systems outside the traditional acquisition process. Many of these systems involve unmanned vehicles and some unmanned aircraft systems (UASs). In 2000, the DoD had fewer than 50 unmanned aircraft in its inventory; by 2012, it had more than 7,100, as shown in Table 1.1 (Gertler, 2012).[1] The size of the Department's investment in these systems today similarly dwarfs prewar levels. In 2000, the DoD spent $284 million on UASs, while the 2010 budget for UASs has grown to over $6.1 billion (GAO, 2010a, p. 1). Figure 1.1 shows the growth of UASs from 1988 to 2013. Figure 1.2 shows projected growth in UAS programs as of 2012.

UASs have two main advantages over manned aircraft: They eliminate the risk to a pilot's life, and they provide capabilities not subject to human limitations. They are also cheaper to procure and operate than manned aircraft. While they minimize risk to operational crews, they introduce new complications and hazards not associated with manned aircraft. While some think of UASs simply as a substitute for manned aircraft, UASs increasingly complement manned aircraft, providing new capabilities for the force to utilize. Combined UAS and helicopter operations are but one example (McLeary, 2012).

Originally, UASs were used to gather intelligence. During the Vietnam War, drones flew strategic reconnaissance missions over denied areas. The Israeli Air Force successfully used UASs during operations in Lebanon in 1982 and for many years led the world in developing UASs and tactics for employment. Subsequently, longer-endurance systems introduced the ability to maintain surveillance on distant and moving targets. More recently, UASs originally designed for reconnaissance have been modified to carry precision-guided weapons to attack ground targets, greatly expanding the role such systems play on the modern battlefield. This also has expanded and complicated the training of UAS crews as full participants in the joint and combined arms battle.

Successful operational tests and demonstrations of the expanded range of UAS capabilities have led to rapid fielding of new systems, often placing unanticipated demands on logistics

[1] See Appendix A for descriptions of the major systems.

and training systems and on field commanders to employ the new systems effectively. UASs must now be integrated into the training programs of the services.

4576 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Building a responsive, effective, and efficient UAS training program is a challenge in a time of reduced budgets. Any new program must be based on a review of existing training capabilities and new investments across the services.

Integrating UASs into the core operations of the DoD presents the kinds of special problems that are common when new technologies appear and clash with existing ways of doing business. Such clashes happen frequently enough that there is a term for such innovations: disruptive technologies. The rapid introduction of UASs into operations in operations Enduring Freedom and Iraqi Freedom and the attendant force structure growth have presented just such challenges (as discussed in Chapter Two). The resulting disruption has contributed to lags in the ability of joint doctrine, tactics, techniques, and procedures (TTP) to keep pace and in the ability of joint training[2] and service-specific managers to develop and execute training programs.[3]

Focus and Approach of this Research

The Deputy Director, Readiness and Training Policy and Programs in the Office of the Under Secretary of Defense for Personnel and Readiness asked RAND to assess the adequacy of UAS training to support current and future requirements. Proposals to resolve service and joint UAS training issues must be informed by a clear understanding of current problems, opportunities for correction, and associated costs and benefits of the corrections. In addition, the current extraordinary pressures on the overall federal budget, including the defense "top line," and the ongoing review of U.S. strategy will likely have implications for force structure and basing, resulting in a number of yet-unknown factors that could profoundly affect the future of UAS programs. These uncertainties notwithstanding, a number of issues must be addressed: (1) a general concept for UAS training; (2) an appropriate framework for addressing UAS training requirements, including the use of simulators; and (3) the airspace requirements necessary for UAS training.

The research reported on here covers UASs in the Army, Navy, Air Force, and Marine Corps as fielded and plans as they existed in 2012. Because of the increasing use of these unmanned systems to support to ground operations, the RAND effort has more closely examined the interface between UASs and operating elements of ground forces. To this end, a team from RAND carried out extensive field visits to understand the current ability of the services to conduct (1) service-specific training and (2) joint training at both home station and joint train-

---

[2] Department of Defense Directive 1322.18, January 13, 2009, defines joint training as "Training, including mission rehearsals, of individuals, units, and staffs using joint doctrine or tactics, techniques, and procedures to prepare joint forces or joint staffs to respond to strategic, operational, or tactical requirements that the Combatant Commanders (CCDRs) consider necessary to execute their assigned or anticipated missions."

[3] Chairman of the Joint Chiefs of Staff Instruction 3500.01G, March 15, 2012, p. C-2, defines service training as follows:

> Service Training: Service Active Component (AC) and RC training (including USSOCOM) is based on joint and Service policy and doctrine. Service training includes basic, technical, operational, and interoperability training to both individuals and units in response to operational requirements identified by the CCDRs to execute their assigned missions.
>
> Joint Training. Training, including mission rehearsals, of individuals, staffs, and units, using joint doctrine and tactics, techniques, and procedures, to prepare joint forces or joint staffs to respond to strategic, operational, or tactical requirements considered necessary by the CCDRs to execute their assigned or anticipated missions.

4577 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

ing facilities. Members of the team interviewed officials involved with UAS training operations at the following Army, Navy, Air Force, and Marine installations and units:

- Beale Air Force Base (AFB), California
  - Global Hawk operations and Distributed Common Ground Station 2
- March Air Reserve Base (ARB), California
  - Air Force National Guard Ground Control Station school
- Holloman AFB, New Mexico
  - (Air Force Predator and Reaper training)
- Fort Irwin, California
  - (Air Force training support unit and selected individuals from the operations group)
- Creech AFB, Nevada
  - (the Joint Unmanned Aircraft Systems Center of Excellence and the operational UAS wing)
- Fort Rucker, Alabama
  - Training and Doctrine Command (TRADOC) capability manager for UASs
- Fort Huachuca, Arizona
  - TRADOC Capability Manager for Intelligence Sensors and the UAS Training Battalion
- Fort Benning, Georgia
  - Maneuver Center of Excellence
- Fort Campbell, Kentucky
  - 101st Airborne Division (Air Assault)
- Marine Corps Base Twentynine Palms, California
  - Marine Corps Air Ground Combat Center (MCAGCC) and two of three active U.S. Marine Corps (USMC) UAS squadrons
- Naval Air Station Patuxent River, Maryland
  - Naval Air Systems Command (Navy and Marine Corps)
- Fort Eustis, Virginia
  - TRADOC Capability Manager for Live Fire Training, Army Capabilities Integration Center, and TRADOC G-3
- North Island Naval Base, San Diego, California
  - Commander, Naval Air Forces.

In addition, the RAND team had extensive discussions with the strategy and planning staffs at U.S. Pacific Command (PACOM) and U.S. Navy Pacific Command concerning rapid acquisition of new technologies, such as the UASs reported on here. In that process, the RAND team gained important insights into the challenges the services face, first in identifying new or disruptive technologies and then in using operational demonstrations or experiments to understand and develop the changes to operational concepts that these technologies would drive.

During these visits, the RAND team talked with operators and support personnel; those who train operators and associated members of the team; those who train and observe the forces that employ UASs in their operations; staff elements concerned with the planning and resourcing of training, both for UAS operators and for the force more generally; and those concerned with the ongoing development of doctrine and concepts of operations for UASs, including their integration into operations.

4578 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Plan for the Report

Chapter Two starts the report with a discussion of disruptive technologies, rapid acquisition processes, and the challenges the DoD faces in integrating UASs into the operations of the military departments. Chapter Three presents a general concept and a framework for training focused on the integration of UASs into military operations. Using the framework, the assessment in Chapter Four considers the current ability of the services to conduct service-specific training at both home station and joint training facilities. This includes a compilation of observations and insights largely gained during our visits to the bases listed above, with our interpretation of their implications for the specification and resourcing of training strategies. Finally, Chapter Five summarizes our research and looks toward the evolving training strategy for DoD in the future. The appendixes present additional material, including a description of ongoing systems, a further discussion of the Defense Acquisition System (DAS), UAS descriptions, and infrastructure considerations and the results of a RAND assessment of training infrastructure.

4579 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

CHAPTER TWO

The Case for and Implications of Unmanned Aircraft Systems Being a "Disruptive Technology"

Over decades, DoD has developed a structured and deliberate approach for the way it acquires new systems, which is formalized in the DAS and the 5000 series of DoD instructions. However, the exigencies of recent military operations have led DoD to develop new technology and acquire and field new systems without going through the steps the defense acquisition process generally requires. While near-term requirements drove such acquisition decisions, these decisions have long-term consequences. Rapid acquisition without a fully developed plan for how the new systems will be sustained over time may well diminish operational effectiveness. A potent example of such an effect is the extent to which the rapid and large-scale introduction of UASs has outpaced investments in the training infrastructure necessary to support the associated operation and maintenance. In the future, personnel will not be able to use or maintain the new systems properly. The Defense Science Board (DSB) made this point forcefully in 2003: "(1) military proficiency is as dependent on the warriors who operate weapon systems as it is on the weapon system technology, and (2) a superb way to waste personnel or system acquisition money is to ignore training" (DSB, 2003, p. 2). Despite the inefficiency of poorly coordinated investments, the DSB found that "systems continue to be created and then fielded with little consideration for the costs that must be incurred during the life cycle to train the weapon's users" (DSB, 2003, p. 44). As it turns out, the difficulty of incorporating new technologies into existing operations and processes is not unusual. It happens frequently enough that there is a term for such innovations: *disruptive technologies*.

The Disruptive Technology Experience in the Business Community

Clayton Christensen introduced the term *disruptive technology* in 1995. He distinguished disruptive technology from what he termed *sustaining technology*. In his nomenclature, a sustaining technology improves the performance of an existing system and does not require significant structural adjustments to processes, organizations, or operational paradigms. Disruptive technologies, however, change the way a business operates (Govindarajan, Kapalle, and Daneels, 2011).

Since the concept was first introduced, a number of studies have focused on ways that enable an organization to incorporate disruptive technologies. Christensen found that many organizations fail to meet the challenges disruptive technologies pose because they focus only on costs and not on how the new technologies change business processes and create new values for customers (Christensen and Overdorf, 2000). As Christensen used the term, *pro-*

4580 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

cesses include the coordination, communication, decisionmaking, and interaction patterns that transform resources into a product. Under normal conditions, processes are stable. They are designed not to be easy to change, and this inertia can impede the adoption and exploitation of emerging disruptive technology (Looy, Martens, and Debackere, 2005). Tellis makes the point that, given limited resources, investments in unfamiliar technologies with unproven returns are opposed because they are seen as "cannibalizing" both resources and customers from established products (Tellis, 2006). Because it is often difficult to introduce such new technologies into existing business units, much of the literature discusses how "spinout" organizations were created to nurture these new technologies (e.g., Henderson and Clark, 1990). For example, in a study of several game-changing technological developments, te Kulve and Smit, 2010, found that successful new product lines usually had a "champion" with "dedicated change strategies" to further the introduction of disruptive technologies.

Unmanned Aircraft Systems: A Case of Disruptive Technology for the Department of Defense

Although DoD operates in a different environment with different incentive structures from those of the business community, it is not immune to the difficulties disruptive technologies have introduced in the private sector.[1] From DoD's perspective, a technology is disruptive when it has the potential to alter the scope and effectiveness of military operations dramatically and is applied in sufficiently large numbers that it can no longer be supported in the same manner as during its initial development (i.e., the military must incorporate its support into its standard logistics and training systems). The UAS qualifies as a disruptive technology on multiple counts. First, as Christensen notes, the advent of the UAS changed the way the U.S. military operated, that is, its "business processes" changed. Second, UASs have broadened the scope of military operations substantially and greatly enhanced the effectiveness of both intelligence processes and strike operations. Finally, they have arrived in sufficient numbers that they now need to be integrated into the standard processes.

As the U.S. went to war in Afghanistan and Iraq, concern grew about the lack of speed and responsiveness in the traditional process for getting new systems into the hands of warfighters.[2] Critics complained about bureaucratic processes that make the traditional system too slow and too risk averse to acquire and field effective solutions rapidly.[3] As late in the conflicts as 2008, Secretary of Defense Robert Gates expressed frustration with the defense bureaucracy, arguing "we must not be so preoccupied with preparing for future conventional and

[1] There are numerous examples of disruptive technologies and how they displaced formerly dominant technologies in both the private sector and the military: Just a few examples are commercial airlines displacing passenger trains, internal-combustion-engine vehicles replacing horse-drawn vehicles, aircraft carriers replacing battleships as the Navy's capital ship, and tanks replacing cavalry.

[2] Appendix B describes DoD's traditional acquisition system.

[3] For example, Lt. General Robert P. Lennox, the Army's Deputy Chief of Staff for Programs and Resources, explained, "This is one of our most common topics of conversation: How do we rapidly field capabilities when technology advances so quickly?" (quoted in Erwin, 2010).

4581 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

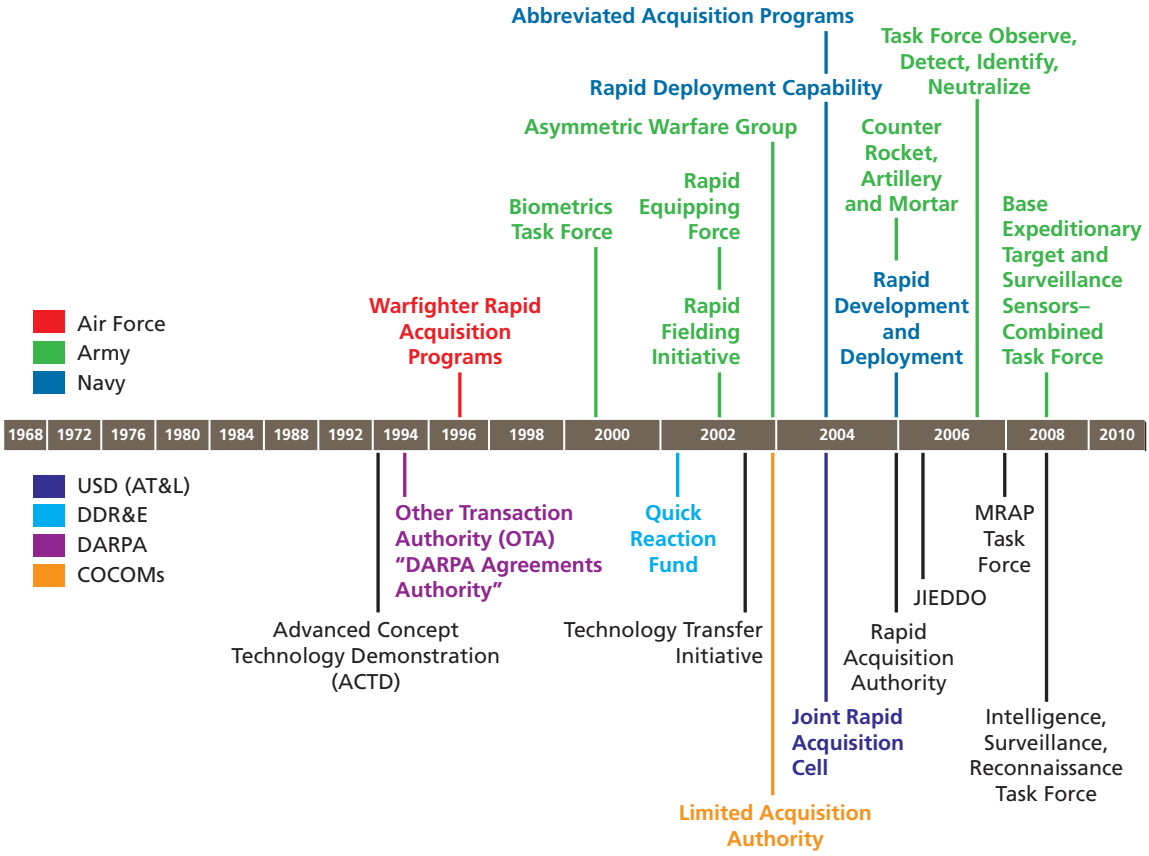
strategic conflicts that we neglect to provide both short-term and long-term all the capabilities necessary to fight and win conflicts such as we are in today."[4]

A Challenge to the Traditional Acquisition System

The virtues of the deliberate and structured traditional acquisition system must be weighed against the fact that the system can take years to field new capabilities. From requirements generation through the DAS and the Planning, Programming, Budgeting, and Execution (PPBE) process, the traditional acquisition system generally takes several years to meet materiel warfighter needs; some systems can take decades (GAO, 2010b). While this long time frame makes some sense for large and complex programs of record, it poses a significant challenge when required capabilities are needed more quickly or are focused more narrowly. This lack of responsiveness has led some observers to argue that the traditional system is not optimized for delivering the full spectrum of desired capabilities. While the system should, in theory, be adaptable for both small and large acquisition programs, it works best in practice for major defense acquisition programs. However, much recent acquisition activity has not been in the form of large programs of record that entail the institutional backing necessary for proper sustainment strategies. The fast rate and large volume demanded for unfamiliar technologies, in particular, have strained the system and pressured traditional acquisition relationships to change.

Rapid Acquisition Programs Met the Challenge

To meet an urgent demand to incorporate new technologies, a series of acquisition processes was created outside the traditional acquisition process and was unencumbered by the prior restrictions designed to mitigate cost, capability, and schedule risk. Unfortunately, while these "workarounds" fostered the fielding of numerous systems, they generally neglected to provide for the institutional sustainment—training and logistical support—needed to facilitate introducing these systems into the force on any basis other than as technology demonstrations. Figure 2.1 captures the proliferation of a selection of these rapid acquisition processes. Below, we discuss several of the more important ones.



Advanced Concept Technology Demonstration

In 1994, in response to recommendations from the Packard Commission and the DSB, DoD introduced the advanced concept technology demonstration (ACTD) (Drezner, Sommer, and Leonard, 1999, p. 23). The Global Hawk UAS, which has found broad applicability in the wars in Iraq and Afghanistan, began as an ACTD. This approach to technological development was intended to improve speed and promote innovation by limiting acquisition hurdles. A system designated as an ACTD could use streamlined management and had reduced oversight requirements (Drezner, Sommer, and Leonard, 1999, p. xiv). ACTDs were intended to bridge the innovation-adoption gap by existing somewhere beyond demonstration of technical feasibility without quite yet becoming major defense acquisition programs. Toward the same end of nudging innovation and eliminating procedural hurdles, in 1994 the National Defense

[4] Gates' distinction reflects what is often a difficult balance between short- and long-term requirements and planning horizons. This creates an institutional tension that has, for example, made the military departments resistant to prioritizing the acquisition of unmanned technology that had near-term applicability but that was not intended to be part of a longer-term vision. See Gates, 2008.

RAND *RR440-2.1*

Authorization Act introduced an authority that allowed the Defense Advanced Research Projects Agency (DARPA), long seen as a mechanism for moving innovative ideas toward materiel solutions, more flexibility in contracting; facilitated use of commercial practices; and waived certain Federal Acquisition Regulations (FARs) and other laws (Drezner, Sommer, and Leonard, 1999, p. 27).

Limited Acquisition Authority

In time of war, new requirements arise that the long and deliberate acquisition system is ill suited to meet. As a result, both Congress and DoD's civilian leadership put in place ad hoc arrangements to seed the development and fielding of new systems. In fiscal year (FY) 2004, Congress granted the Secretary of Defense the authority to delegate a limited acquisition authority (LAA) to Joint Forces Command (JFCOM) to speed the research and development and limited fielding of new systems (GAO, 2007a). However, LAA is an authority, rather than a program, and does not translate into budgeted funds.[5] In the first three years of the authority,

[5] JFCOM had to reallocate funding from its own budget or gain funds from another DoD organization. Over one-half the programs JFCOM supported came from its own budget. In addition, after the systems were acquired, funds were not

4583 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

JFCOM used the LAA to support six projects. After that, LAA activities slowed significantly, a trend GAO suggests may be linked to lack of access to funding (GAO, 2007a, p. 3).

Joint Rapid Acquisition Cell

The Joint Rapid Acquisition Cell (JRAC), also established in 2004 by the Deputy Secretary of Defense and organized in the Office of the Under Secretary of Defense for Acquisition, Technology, and Logistics, constituted another rapid acquisition program. The intent of this cell was to meet new requirements that the combatant commanders (COCOMs) identified as operationally critical; the COCOMs' prominent role in JRAC has led some to tag it the "COCOM's acquisition process" (Middleton, 2006, p. 19; see GAO, 2010b, p. 1). During its initial three years, JRAC supported 24 programs, at a cost of $335.5 million.[6] These funds came primarily from war supplemental appropriations and were not part of the military departments' programs or budgets. A 2009 DSB report found that this meant that "these programs continue to lack serious institutional commitments; very little is being built into the service or other DOD budgets for these programs" (DSB, 2009, p. 6). While JRAC required a life-cycle plan as part of the acquisition process, the DSB found this planning inadequate. Training relied more "on learning on the job with little emphasis on support, training, and sustainment." (DSB, 2009, p. 6). The typical institutional support in the services that is needed to fund, for example, investments in the training infrastructure does not exist for every rapidly acquired system.

Rapid Equipping Force

In 2002, the Army established the Rapid Equipping Force (REF), whose mission was to equip operational commanders with technological solutions to urgent war needs in no more than six months (DSB, 2009, p. 12). In 2005, the REF was made permanent (Kennedy, 2006, pp. 43–45). The organization began with a staff of 14 personnel, which expanded to 150 by 2007 (Dietrich, 2007, p. 5). In 2005 alone, it purchased more than 20,000 items, including robots, surveillance systems, digital translators, and weapon accessories (Dietrich, 2007, p. 6). The REF supported the rapid acquisition and fielding of a widely adopted technology called PackBot, which became a vital tool in the identification and defusing of deadly improvised explosive devices. The REF also supported other unmanned and robotic technology, including the development of the battery-powered, hand-launched, and camera-equipped Tactical Mini Unmanned Aerial Vehicle (UAV) in 2005. The REF project leader described that UAV as a technology that allowed soldiers to "go into situations knowing what's in front of them" (Ainsworth, 2005). REF purchased the mini-UAV commercially and, after some software modifications, quickly had it ready for theater operations (Miles, 2005). Yet, insufficient consideration for back-end support reportedly plagued early REF efforts, and steps have been taken to ameliorate the difficulties. COL Gregory Tubbs, REF director, conceded that the early ad hoc "wild west" days of REF logistical support were a challenge (Kennedy, 2004).

---

readily available for long-term sustainment. A 2005 report from the Center for Strategic and International Studies called for providing rapid acquisition approaches with more-secure funding: "Urgent requirements will be met much faster if they can be resourced without taking funds from existing programs" (Murdock and Flournoy, 2005, p. 98).

[6] The process begins when a COCOM identifies and validates an urgent operational needs statement (or a joint urgent operational needs statement for joint requirements), defined as "urgent, combatant commander-prioritized operational needs that, if left unfilled, could result in loss of life and/or prevent the successful completion of a near term military mission." *Immediate warfighter needs* were the urgent operational needs statements certified as requiring a solution in 120 days or less. For a given system, JRAC is authorized to expend $365 million in research, testing, development, and evaluation funds and up to $2.19 billion in procurement. See GAO, 2007a, p. 12.

4584 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Intelligence, Surveillance, and Reconnaissance Task Force

The high value placed on UASs, specifically in new intelligence, surveillance, and reconnaissance roles, can be seen in the robustly funded Intelligence, Surveillance, and Reconnaissance (ISR) Task Force, which supported the fielding of numerous unmanned systems. In spring 2008, Secretary Gates established this task force to expedite the fielding of ISR assets to combat areas (Sherman, 2008). The task force originally had a 120-day charter; two years after the task force's founding, the secretary announced that it would become a permanent part of the Office of the Under Secretary of Defense for Intelligence (Bennett, 2010). Its mission was to address unmet ISR requirements and to rapidly acquire and field capabilities by coordinating activities and pursuing innovative solutions (Loxterkamp, 2010). The ISR Task Force was to recommend ways to maximize the availability of systems in the inventory and to boost acquisition of additional systems (Best, 2010, p. 17). In FY 2008 alone, Congress approved the reprogramming of $1.3 billion based on ISR-TF recommendations (GAO, 2008b). Among the systems the task force supported were the Navy's unmanned MQ-8 Fire Scout and the fielding and sustainment of 50 unmanned Predators.

Informal Approaches to Rapid Acquisition

The formal approaches highlighted above support rapid acquisition in a variety of ways. Some consist of an acquisition authority but no money (LAA); some consist of funding (REF); some facilitate stronger requirements inputs (JRAC); and some, like Special Operations Command (SOCOM), have everything. Yet importantly, some rapid acquisition has taken place outside even these ad hoc institutional arrangements. For example, in one case, the personal relationships enabled rapid acquisition of command and control (C2) systems. In another, ADM James Stavridis instituted a "culture of innovative thought" into U.S. Southern Command (SOUTHCOM) by developing his own in-house technical capabilities through a process he called Linking Plans to Resources, an approach aiming to associate capabilities with specific solutions (Hicks, 2008, p. 33). He chartered the Joint Innovation and Experimentation Directorate, tasking it with improving how the command trains, fights, and does business (Stavridis, 2010, p. 177). This small innovation staff was to "research, explore, and test emerging technologies available commercially or through Federal research centers" (Stavridis, 2010, p. 89). The directorate was to take the lead in identifying new and creative ways of meeting the command missions, and was given the primary responsibility for "developing validated solutions into an initial operational capability," materiel or nonmateriel (Stavridis, 2010, pp. 178–179). These innovations, looking for better ways to link requirements to resources and developing in-house capabilities for acquiring solutions, reflected new acquisition roles.

PACOM's version was the Plans to Resources to Outcomes Process, which helped in the development of the command's integrated priority list. PACOM also developed its own in-house means of meeting requirements (Murdock and Flournoy, 2005, p. 40). PACOM's Joint Innovation and Experimentation Division uses the integrated priority list to develop rapid, innovative solutions for filling the gap and injecting them into PACOM exercises. Similarly, in 2009, U.S. European Command appointed a special assistant for innovation and technology to field equipment for the war in Afghanistan. Navy Captain Jay Chestnut, special assistant in charge of the project, explained that European Command "knows that 'big acquisition' [the traditional system] is trying to do the right thing but sometimes you need someone working on the side, looking innovatively" (Francis, 2009).

4585 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

In addition to the development of in-house approaches, informal rapid acquisition has also involved forging relationships between the COCOMs and technical expertise outside the military departments. As described by Stavridis, SOUTHCOM worked to both build in-house staff and forge relationships with a "technological base" external to the organization. He highlights, in particular, the partnership with DARPA, in which DARPA pursues "exploration and technology where risk and payoff are both very high, and where success may provide dramatic advances" to the SOUTHCOM mission (Stavridis, 2010, p. 89). Included in Admiral Stavridis' list of outcomes of this productive symbiotic relationship with DARPA are unmanned aerial craft and unmanned surface vessels.

The Use of Fast Track Authorities Can Cause Problems

For acquisitions to be "rapid," certain aspects of the traditional acquisition process have been left out. In many cases, it is the training and support planning that have been omitted. In 2008, the GAO reported that the

> rapid fielding of new systems and the considerable expansion of existing Air Force and Army programs has [sic] posed challenges for military planners to fully account for UAS support elements, such as developing comprehensive plans that account for personnel and facilities needed to operate and sustain programs." (GAO, 2010a, p. 37)

Because many of these programs do not pass through the system development and demonstration phase or a logistics supportability analysis, the data needed to generate training and support planning and ultimately guide investment decisions are unavailable. In 2010, the GAO found that the Air Force had not developed a servicewide plan that identified the number of personnel to be trained, the specific training required, and the resources necessary to establish a dedicated UAS training pipeline (GAO, 2010a). The Air Force has reportedly been struggling to staff significant increases in unmanned systems (Baldor, 2010). Going from a handful of drones in 2007 to 45 by 2010, with plans to operate 50 by 2011 and 65 by 2013, had created significant resource challenges for the department. These resource challenges became heavily pronounced with the "surge" in UAS requirements for operations in Libya and Afghanistan beginning in March and extending into summer 2011. The Air Force, to fulfill combat air patrol (CAP) requirements, stood down a portion of its formal training structure to form three CAPs (U.S. Air Force, 2011). As the Air Force's Deputy Chief of Staff for Operations, Plans, and Requirements explained in 2010, the "number one manning problem in our Air Force is manning our unmanned platforms" (Baldor, 2010).

The GAO similarly found that the Army's personnel authorizations were insufficient to support UAS operations. The Army has determined on at least three separate occasions since 2006 that Shadow UAS platoons did not have adequate personnel to support the near-term and projected pace of operations (GAO, 2010a). Officials from seven Army Shadow platoons in the United States and Iraq told the GAO that approved personnel levels for these platoons did not provide an adequate number of vehicle operators and maintenance soldiers to support operations (GAO, 2010a). Army officials told the GAO that currently approved personnel levels for the Shadow platoons were based on planning factors that assumed that the Shadow would operate for 12 hours per day with the ability to extend operations to up to 16 hours for a limited time (GAO, 2010a). However, personnel with these platoons told the GAO that UASs in Iraq routinely operated 24 hours per day for extended periods (GAO, 2010a). Army officials

4586 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

also reported that combat brigades and divisions require additional personnel to provide UAS expertise to assist commanders in making effective use of new technological systems (GAO, 2010a).

UASs exemplify the challenges of integrating training and sustainment considerations outside the strictures of the formal acquisition process. Ad hoc rapid acquisition processes were able to field UASs rapidly, but because of the nature of these processes, the fielded UASs lacked sustainable institutional support and funding needed for future investments in the training infrastructure. Frequently, the services try to sustain and support these programs by relying on contractors, just as they did during system development.[7] Of course, employing contractors to provide training is not in itself a problem. But it does reflect the extent to which training has been more about expediency than about effective institutionalization, particularly with regard to the imperative to train as we fight and the need to fully appreciate the need to integrate UAS training across the full spectrum of combat units.

[7] For example, the Air Force continues to rely on contractors to perform a considerable portion of UAS maintenance. For example, contractors perform approximately 75 percent of organization-level maintenance requirements for the Air Combat Command's Predator and Reaper UASs. See GAO, 2010a.

4587 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

CHAPTER THREE

Training Concept and Framework for Unmanned Aircraft Systems

We will begin by discussing the general ideas that should guide UAS training—the training *concept*. Then, we will consider how the parts identified in the concept fit together into a conceptual structure for that training—a training *framework* designed to enhance combat power and other operational capabilities. Note that the term *UAS* can be misleading. In fact, there is not a single UAS but rather a family of aircraft that share the common feature that they fly without a pilot on board.[1] These aircraft have very different personnel and training requirements. The vast majority of UASs support ground operations, and that will be our primary focus. As noted in Table 1.1, ground forces—the Army and Marine Corps—own many of these systems themselves, but the Air Force owns some of them and often flies them in support of ground operations. UASs are sometimes flown in support of conventional ground operations and sometimes in support of special operations. Our main focus is on support of conventional forces. UASs are now also being developed that will support maritime forces, and we also consider them.

Training Transformation, Joint Doctrine, Joint Operations, and UASs

Large military operations today are usually joint operations requiring and emphasizing the interdependence of the services. It follows naturally that joint doctrine, joint concepts of operation, and joint TTP would provide focus for training. Accordingly, the DoD's Training Transformation Implementation Plan requires that in order to "improve joint force readiness" there be a "unity of effort in training across Services, agencies and organizations."[2] That said, joint training guidance and publications generally provide guidance direction on the coordination and collaboration among elements of different services to optimize the joint employment of their various capabilities, and not on the employment of any one, specific system or even family of systems, such as UASs.

Clearly, training does not take place for the sake of training; it should be driven by doctrine. Thus, in line with the general focus described above, JP 3-0 (2001) "establishes the framework for our forces' ability to fight as a joint team," but nowhere does the document discuss the management of UASs or any other specific system. Moreover, nowhere in any other joint publication is there a grand doctrine for the employment or management of UASs on

[1] In 2014, the Air Force republished its vision for its system, replacing the term *unmanned aircraft systems* with the term *remotely piloted aircraft* (RPA) (U.S. Air Force, 2014, p. iii).

[2] See Director, Readiness and Training Policy and Programs, 2006, p. 5.

4588 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

the battlefield. However, the services have agreed to a set of TTP to be incorporated into their respective training programs. They describe these as a "multiservice" rather than a joint TTP, thereby avoiding doctrinal issues on how to deploy and manage UAS even as the services support joint operations.

Air Force Maj David Buchanan explored the difficulty of developing a joint doctrine for UASs in a 2010 Naval War College paper, summing up the difference this way: The Air Force believes in centralized control, and the Army believes in decentralized operations. He noted that the

> Air Force's proposal to assume executive agency for all medium- and high-altitude UASs in March 2007 was an attempt to establish unity of command and increase UAS efficiencies. … The Army's position … was that a single-service approach to UAS employment would infringe on the effectiveness of UASs in combat.
>
> The Air Force's centralized approach may result in a more efficient allocation of limited UAS assets, but that efficiency comes at the cost of combat effectiveness. The Army's answer to regain effectiveness has been to decentralize command and control for its unmanned aircraft systems. Ground commanders rely on UASs to provide timely, relevant, and useful intelligence without the lengthy processing and dissemination associated with the Air Force's centrally controlled, theater-wide assets. The Army's Training and Doctrine Command noted that the joint (CAOC [combined air operations center]) solution to meeting the high demand for these low-density assets has been ineffective, arguing against relying on the JFACC [Joint Force Air Component Commander] for UAS coverage. (Buchanan, 2010, p. 7).

JP 3-55.1 reflects a more service-centric notion of jointness.[3] When it was written in 1993, UASs were primarily thought of as reconnaissance, surveillance, and target acquisition (RSTA) assets. As envisioned then, mission planning was to be "based on the requirements of the supported unit," with due consideration for "airspace management conflicts" (JP 3-55.1, 1993, p. II-9).

Over time and with practical experience in Iraq and Afghanistan, the utility of UASs has expanded from consisting primarily of ISR to include armed surveillance and armed overwatch (e.g., for movement support and area security), targeting, communications support, attack, strike, and engagement; in the future, it will further expand to encompass logistical support and casualty evacuation missions. This expanded range of missions presents a challenge that was addressed in 2011 with the publication of a common set of multiservice TTP (MTTP).[4] Each of the four services has agreed to incorporate the MTTP into its respective training. The agreed-to MTTP document requires that

---

[3] JP 3-55.1, 1993, p. II-1, states that the

> [p]rimary mission of UAS units is to support their respective Service component commands as a tactical RSTA system providing the commander a capability to gather near-real-time data on opposing force position, composition, and state of readiness. However, as is the case with all assets and groupings within the joint force, the joint force commander (JFC) has full authority to assign missions to and task component UAS to conduct operations in support of the overall joint force.

[4] Reflecting the multiservice, rather than joint, nature of the document, each service has assigned its own number to it: Army Tactics, Techniques and Procedures 3-04.15, Marine Corps Reference Publication 3-42.1A, Navy Tactics, Techniques and Procedures 3-55.14, and Air Force Tactics, Techniques and Procedures 3-2.64. From here onward in this report, we will refer to the document simply as "the MTTP."

4589 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

> group 3-5 UAS operations will be coordinated with the ACA (airspace control authority) and included in the ACO (airspace control order), SPINS (special instructions) and the ATO (air tasking order) in order to separate UASs from manned aircraft and to prevent engagement by friendly air defense systems. (MTTP, 2011, p. 12)

Table 3.1 describes the five UAS groups. The TTP for UASs that the services agreed to recognize that UASs may either be controlled by a centralized or joined C2 node (MTTP, 2011, p. 15) or be operated independently and that the service component commander may retain operational control of UASs (MTTP, 2011, p. 16), thereby avoiding the doctrinal issue that divided the Army and Air Force. In general, UAS control during the execution of an operation should be at the lowest tactical level to streamline the decision time lines and thus optimize responsiveness. The MTTP provides vignettes to help supporting and supported units understand how to incorporate and use available UAS assets more effectively. It should also be noted that no distinction is made between organic and nonorganic UAS support (MTTP, 2011, p. 40).

At least for the foreseeable future, each service will continue to field UASs and must bring to the fight forces fully capable of operating these aircraft and integrating their capabilities into joint operations. While some overarching doctrinal issues remain unresolved, the common procedures the services have agreed to and train for will remain the foundation on which UAS operations must be built, just as they are for military operations more generally. In this way, rather than being the foundation for UAS training, joint training is the apex of such training, which must be firmly grounded on the UAS training each service gives both its supported units and the supporting UASs.[5] This is the main focus of this report.

The UAS Training Concept: A General Notion for UAS Training

The contribution that UASs make to the modern battlefield results from a synergy among the platforms themselves, those who operate the platforms, and those who incorporate the UASs into the battle. Combat power cannot expand unless all three work together. A platform flown

Table 3.1
UAS Tiers by Service

Group	Capability	Examples
I	Hand-launched, self-contained, portable systems employed for a small unit or base security.	RQ-11A/B Raven
II	Small to medium in size and usually support brigade and intelligence, surveillance, reconnaissance, and target acquisition requirements.	ScanEagle
III	Operate at medium altitudes with medium to long range and endurance.	RQ-7 Shadow
IV	Relatively large UASs that operate at medium to high altitudes and have extended range and endurance.	MQ-1 Predator
V	Large, high-altitude, long-endurance UAV platforms	RQ-4 Global Hawk

SOURCE: DoD, 2011, pp. D-2 and D-3

[5] The terms *supported unit* and the *supporting UAS* are basic constructs of MTTP, 2011, p. 9.

4590 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

by a skilled pilot does not add anything to the battle unless those on the ground who are engaged know how to exploit the information and other support the UAS provides. Similarly, if the pilot and payload operator cannot respond to the ground commander, the support they provide will not be what the commander needs. Only when all three work together will UASs be effective as a force multiplier. This can be achieved through training and practice that brings the platform, the operator, and the users together, starting at home station and progressing through ever-more-complicated exercises at the major training centers, such as the National Training Center (NTC) at Fort Irwin, California; the MCAGCC at Twentynine Palms, California; and the Joint Readiness Training Center at Fort Polk, Louisiana. Accordingly, how to achieve this synergy is the fundamental organizing concept for UAS training.

Let us be clear. The organizing concept developed here is not built around the training of a UAS pilot or payload operator per se. Their proficiency is certainly a necessary condition for UAS operations but is not, by itself, sufficient to enhance combat power. Enhanced combat power is achieved through the synergistic process that brings the platforms, the operators, and the users together. It starts at home station with small UASs and builds through the echelons of the ground forces as larger UASs are integrated into the combat operations of higher-echelon formations. Properly done, the maintenance or refinement of proficiency levels for UAS pilots and payload operators will be achieved incidental to the training that should take place with ground forces. But even before training can start, the services must decide how these systems will be used and how they will be incorporated into the force.

A Concept of Operations for UASs Is a Prerequisite for Training

As noted in the previous chapter, UASs are a classic disruptive technology. Integrating them into existing military operations is still a work in progress. This creates a problem for those charged with building training programs because, before training can start, the services must decide how these systems will be used and how they will be incorporated into the force. The services are still learning how best to use these new systems and the capabilities they provide. Each service is doing it differently.

Army

Initially, the UAS was thought of as just another platform for RSTA sensors, and the intelligence community was the proponent in the Army. In 2003, proponency for UASs transferred from Army Military Intelligence to the Army Aviation Branch. Since then, the UAS role in the Army has been changing from the relatively passive intelligence-gathering mission to the more active scout-reconnaissance and attack missions. One consequence of this transition is that UAS operators frequently team with manned aircrews to perform the scout-reconnaissance role. However, UAS operators and manned aircraft crews are currently separate communities and undergo separate programs of training.

At another level, the Army is experimenting with how to support the Raven, a small, hand-launched UAV. There is no dedicated military occupational specialty (MOS) for Raven operators. Being a Raven operator is an additional duty that requires additional training. Master Raven Training, a three-week train-the-trainer course, takes place both in the classroom and in the field. Students are taught how to maintain and operate the equipment and how to judge when and when not to fly. The plan calls for the trainer to return to home station and train squad-level personnel to operate the Raven.

4591 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Navy

The Navy has a different scheme for integrating the Fire Scout UAS and Broad Area Maritime Surveillance (BAMS) into the fleet. Typically, maintainers and pilots for Fire Scout have already gained technical training on manned helicopters. The Fire Scout–specific training is six weeks long and takes place at the Fire Scout Training Center at Naval Air Station Jacksonville, Florida (U.S. Army Maneuver Center of Excellence, undated).

The Navy's version of the Air Force's Global Hawk is the MQ-4C Triton, developed under the BAMS program. While the Navy continues to fly it to refine TTP for use in a maritime environment, the concept is for it to be integrated into active Navy maritime patrol units to complement the P-8 Poseidon, Boeing's 737–based multimission maritime aircraft, a traditional manned aircraft.

Air Force

The Air Force has yet another concept of operations that emphasizes remote split operations and reaches back to the Global Operations Center at Creech AFB, Nevada. Today, six operations centers in the continental United States (CONUS) support five launch-and-recover units in theater. Integration with tactical units is through tactical air control parties (TACPs) at the division, brigade, and battalion levels, and often at lower levels when supporting special operations forces (SOF). The TACPs coordinate directly with the Predator operations center via ultrahigh frequency radios on the aircraft or via satellite communications. As with other Air Force assets (and many air assets of other services), UAS assets are assigned to support ground commanders through the ATO. In the Air Force, the UAS pilots and payload operators are commissioned officers.

Marine Corps

The Marine Corps has dedicated UAV squadrons located at the MCAGCC at Twentynine Palms, California, and recently at Camp Pendleton, California. In the Marine Corps, enlisted Marines are responsible for almost every facet of the mission, from flying the aircraft and operating the payload camera to takeoffs and landings.

Summary

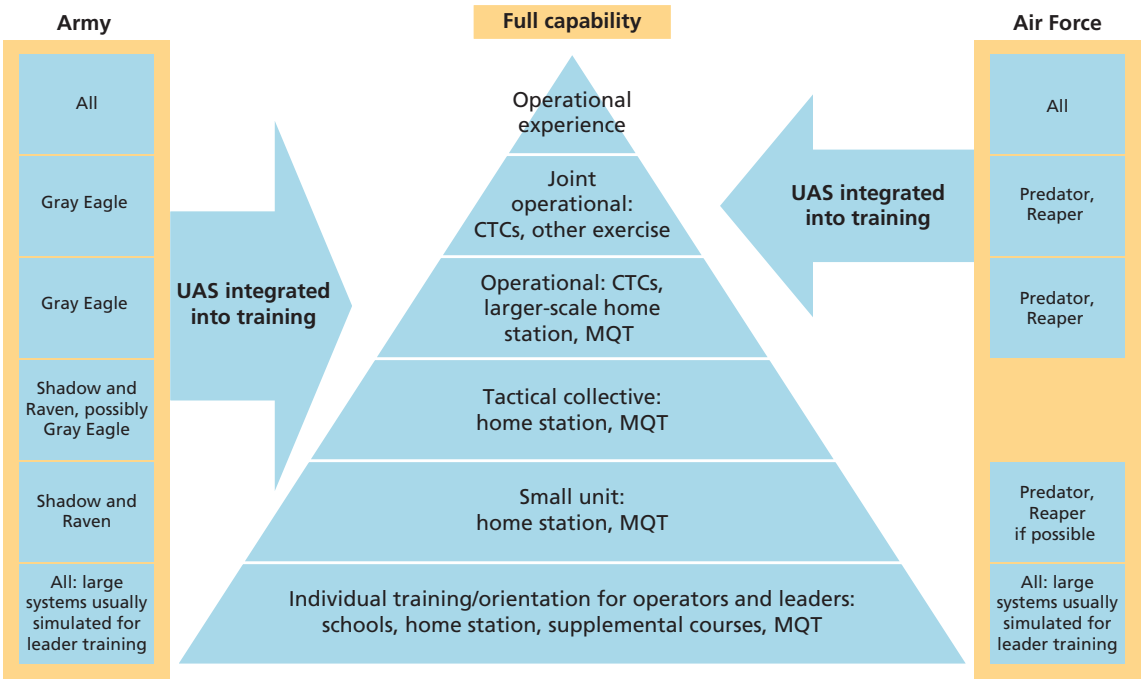
Even as the services are experimenting with the best way to use UASs and to integrate them into their forces, the overall purpose for UAS training should be clear. It is to increase combat power through the synergistic process that brings the platforms, the operators, *and the users* together. Putting these pieces together is the primary theme of the training framework we present.

Training Framework for Tactical UASs

The focus of the UAS training framework we offer is the enhancement of combat power, which starts with well-trained individuals who learn to work as a unit and ultimately leads to units that coordinate their efforts to produce military force. As we have seen, however, each service uses UASs differently.

Moreover, the great variety of UASs adds to this complexity. UASs are classified into tiers. Military planners designate the various individual aircraft elements in an overall usage plan using a tier system. The tiers do not refer to specific models of aircraft but rather to roles the

4592 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING



aircraft typically fill. Table 3.1 shows the UAS groups and their roles and offers the examples of systems assigned to them.

The following discussion of training frameworks refers primarily to tactical UASs and not such Tier V systems as Global Hawk and its naval variant, the BAMS-D Triton.

The Training Framework for Ground Combat: Army, Marine Corps, and Air Force

The pyramid shown in Figure 3.1 represents our idea of the training framework to enhance combat power for the Army and Marine Corps, integrating organic UASs and Air Force UASs, when available, in support of ground forces. It is a graphic representation of the synergy achieved through training and practice that brings the platform, the operator, and the users together, starting at home station and progressing to higher echelons and ever-more-complicated battle exercises. The services have committed to align their training with the agreed-to MTTP. As with any good framework, the UAS framework must have a strong base. The base of this framework, represented by the lowest level of the pyramid, includes the initial and individual skills training of those who operate, maintain, and use the systems. The higher levels of the pyramid roughly align with the echelons of ground forces from the platoon or squad level through the company level and moving up to battalions, then to brigades. Each level incorporates the C2 of subordinate units to create combat power that is more than the sum of its parts. A battalion is more than just a collection of companies, each of which is more than just a collection of platoons and squads. In creating this combat power, the battalion utilizes UASs that are not normally available to its subordinate companies. In this way, the battalion and its UASs are "combat multipliers." This increase of combat power is repeated as we move up the pyramid to higher echelons each supported by the UASs that are organic to that

Figure 3.1
UAS Training Framework for Army, Marine Corps/Air Force Joint Combat Operations

RAND *RR440-3.1*

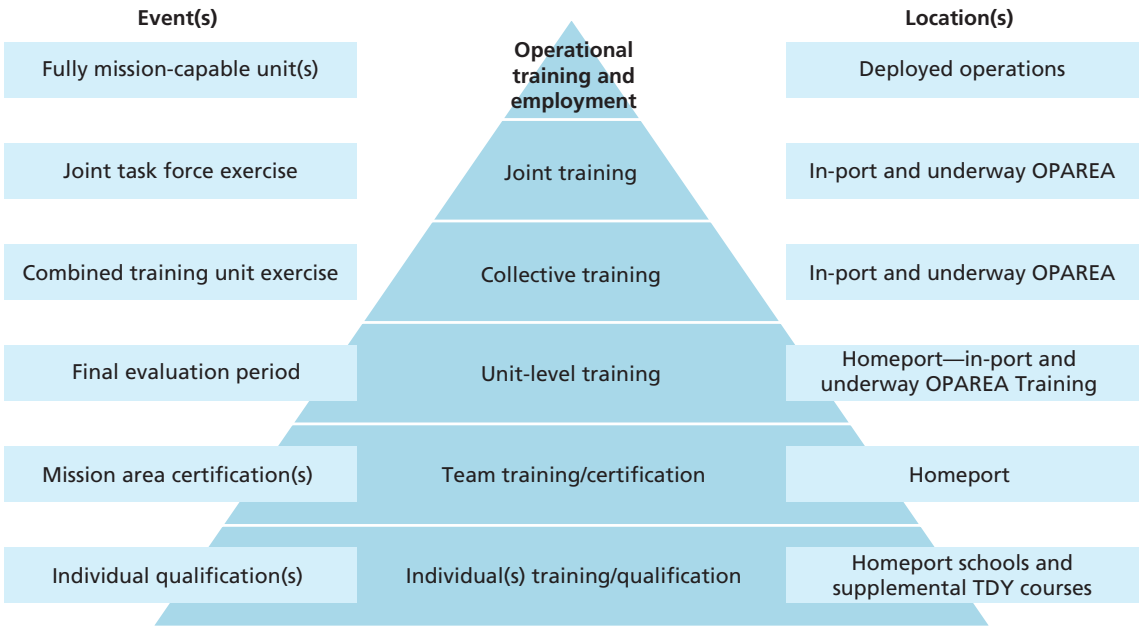
tier. The two different-sized arrows, coming in from the left for the Army and from the right for the Air Force, show the specific UASs and the echelons they support.

In our concept of the training framework for UASs, the ground force systems—those of the Army and Marine Corps—and Air Force systems are "stacked" along the sides and paired with the level of the pyramid they support. The entries at each level of the pyramid identify the type of training that needs to be accomplished and where that training takes place. For example, small-unit training, at the lowest level of the squad and platoon, incorporates the Raven UAV and is accomplished at home station. Company training, which generally entails C2 of four platoons, is also accomplished at home station. The individual platoons may each be using their own Ravens, and the company commander may have access to the information from a Shadow UAS.

This process is repeated at home station with companies being brought together under the C2 of the battalion commander and his staff. During a battalion exercise, the battalion commander will generally be able to task the Shadow UASs either individually or as part of the combat support from assigned Army aviation. In some cases, this may include information provided by the Gray Eagle UAS. In some instances—these have historically been very rare—available Air Force UASs, such as Reaper or Predator, may support home station battalion exercises.

Brigade-level training can be carried out at some home stations, but the maneuver combat training centers (CTCs) generally provide a better venue. All available Army UASs will support these training exercises, from the small Ravens to the larger and higher-flying Gray Eagle, when available. In addition, it is at this level and during these exercises that joint Army–Air Force support is usually integrated to include close air support (CAS) and support from Air Force UASs.

Not shown on the pyramid is the training needed to meet the certification requirements of UAS operators. Such requirements will normally be met incidental to their training with ground forces. For example, Shadow operators need to operate their equipment 4.5 hours per month to maintain their certification. It is expected that they will be spending more than that supporting ground units during home station training. Operators not actively engaged with the training of ground units can achieve the needed proficiency training using the same training equipment as during their initial skill training.



The Training Framework for Fleet Operations

A similar pyramid also represents our framework for Navy UAS training (Figure 3.2). It differs from the previous pyramid in that the Navy does not have a hierarchy of systems introduced at higher echelons of command. At the tactical level, the only UAS the Navy has is Fire Scout, which will be introduced into fleet operations following a similar path as discussed above. As with land forces and the systems that support them, combat proficiency is generated through the synergy of the platform, operators, and staffs that incorporate the UASs into the battle planning. Initial operator training is the base of the pyramid and takes place in the schoolhouse in the vicinity of the homeport. Operational training occurs under way in fleet operating areas. The Navy trains continuously, and the training continues through the operational use of UASs when the units are deployed.

UAS operators and maintainers require initial training to obtain the skills needed for operational effectiveness. As individuals become qualified as UAS operators and maintainers, they undergo team training to achieve mission area certification. For example, UAS operators

4594 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Figure 3.2
UAS Training Framework for Navy Tactical UAS

RAND *RR440-3.2*

may be linked to and integrated with an antisurface warfare mission team to support certification for the surface warfare mission area. For ships, unit-level training occurs both in port and under way and culminates in a final evaluation period. During that evaluation, the immediate superior in command evaluates the ship in all mission areas to determine that it is ready for advanced phase training. The final evaluation period comprises in-port and underway training events geared to assess the unit's ability to operate independently.

Collective training occurs after the final evaluation period, when the ship begins to operate with other units and staffs. During this time, the ship conducts operations with and becomes an integral part of a carrier strike group (CSG).[6] Collective training is a combination of in-port and underway training events and culminates in a combined training unit exercise evaluated at the fleet commander level. The Navy is in the process of developing its UAS tactics and procedures and plans to integrate UAS training into predeployment preparations.

Deployed naval ships and units must also operate in a joint environment. After completing a combined training unit exercise, a deploying CSG conducts a final exercise with elements of other services (e.g., Air Force aircraft) to demonstrate its ability to communicate and operate effectively in joint warfare. Joint training is conducted both in port and under way. An underway joint task force exercise is the culminating event, with Navy units operating with forces of the other services; on satisfactory completion, units are deemed ready to deploy. Units then continue the operational training and employment of their systems en route to their deployed operational areas.

[6] While we address surface units as being part of a CSG, surface units can also deploy independently, with other ships, or with an expeditionary strike group.

4595 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Navy units deployed to 5th Fleet do have experience with BAMS–Demonstrator (BAMS-D), the predecessor to the Triton, and a variant of the Air Force's Global Hawk. Despite being a demonstrator, BAMS-D was deployed to meet surveillance needs in the 5th Fleet. Navy strike groups operating in 5th Fleet were provided with imagery and data feeds from BAMS-D and used these data to build a common operational picture, which increased situational awareness. The BAMS-D was integrated into actual fleet operations and provided near-real-time updates for surface surveillance. Units learned to use BAMS-D "on the fly," by processing, exploiting, and disseminating imagery and sensor data; building the surface picture; and increasing the positive identification of surface contacts in the area of operations.

As UAS assets are fielded, they will be incorporated to a greater degree into predeployment training and increase opportunities to train and hone the tasking, collection, processing, exploitation, and dissemination of UAS sensor data.

Applying the Training Framework

The training framework presented here focuses on the synergy among three key elements: the platform itself, those who operate the platform, and those who incorporate UASs into the battle. The framework emphasizes using UASs to enhance warfighting proficiency. It provides a useful tool for organizing and evaluating training options and assessing the current state of training and plans for improvement. As discussed in the next chapter, we used the framework to assess the state of UAS training, as it existed in 2012.

4596 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

CHAPTER FOUR

Assessment of the State of UAS Training in 2012: Service and Interoperability Training and the Role for Simulators

For more than a decade, UAS training has concentrated on preparing UAS pilots and payload operators to support ongoing operations in Afghanistan and Iraq. This remained true in 2012 and 2013, and the services continue to evolve how best to use these systems and integrate them into ongoing operations. With the operations in Afghanistan winding down, the services must now integrate all facets of UAS training, including the infrastructure for training addressed in Appendix C, into a largely CONUS-based inventory of UASs that continues to grow, even as real-time operations continue for some systems.[1] Moreover, operational demands and technical innovations will continue to evolve and affect training and organizational requirements. As a result, UAS training and training support programs must be viewed as works in progress.

In assessing the current state of UAS training, using the UAS training framework discussed in the previous chapter, we view proficiency in flying UASs not as an end in itself but as only a means to an operational end: accomplishment of a military mission. As noted, this is achieved through the synergistic use of UASs with the forces they support, in ways similar to those in which the timely integration of intelligence or the delivery of fire support is accomplished in combat operations. This convergence requires full integration of UASs into the collective training of operational forces, attendant training and education for leaders and staffs, and the integration of lessons learned from previous and ongoing operations into education and training programs.

The preceding should by no means be construed to understate the need for training those directly involved in the operation of UAS—among them pilots, crews, support personnel, and those who maintain the aircraft and communications systems. Such training, both to develop and to maintain proficiency in the operation of UAS, is critical for the overall success of a UAS training strategy. But proficiency in these areas is not in itself sufficient. Full understanding of UAS integration, from the smallest to the largest systems at every echelon, as outlined in the previous chapter, is also necessary.

To be clear, members of the UAS community not only must understand how to operate their systems—a challenge largely being met successfully—but must also be familiar with the fundamentals of the operations they support and how their capabilities contribute to the successful accomplishment of the mission. Similarly, battle staffs must fully understand the many capabilities of UASs, how these capabilities supplement or complement other capabilities available to the joint force, and how best to integrate the capabilities into their operations.

[1] The Air Force UAS community believes high demand for its systems—Predator and Reaper—will persist, with requirements to support other kinds of demands increasing as demands for support of ground maneuver operations decrease.

4598 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

This chapter assesses the state of training for UASs across the ground, air, and sea forces. It discusses information, observations, and insights gained from a wide variety of sources but mainly through visits to a select number of service bases in 2012. During these visits, the RAND team talked with operators and support personnel; those who train operators and associated members of the team; those who train and observe the forces who employ UASs; staff elements concerned with the planning and resourcing of training, both for UAS operators and for the force more generally; and those concerned with the ongoing development of doctrine and concepts of operations for UASs, including their integration into operations. What follows is a compilation of the observations and insights from these individuals and our interpretation of the implications for the specification and resourcing of training strategies.

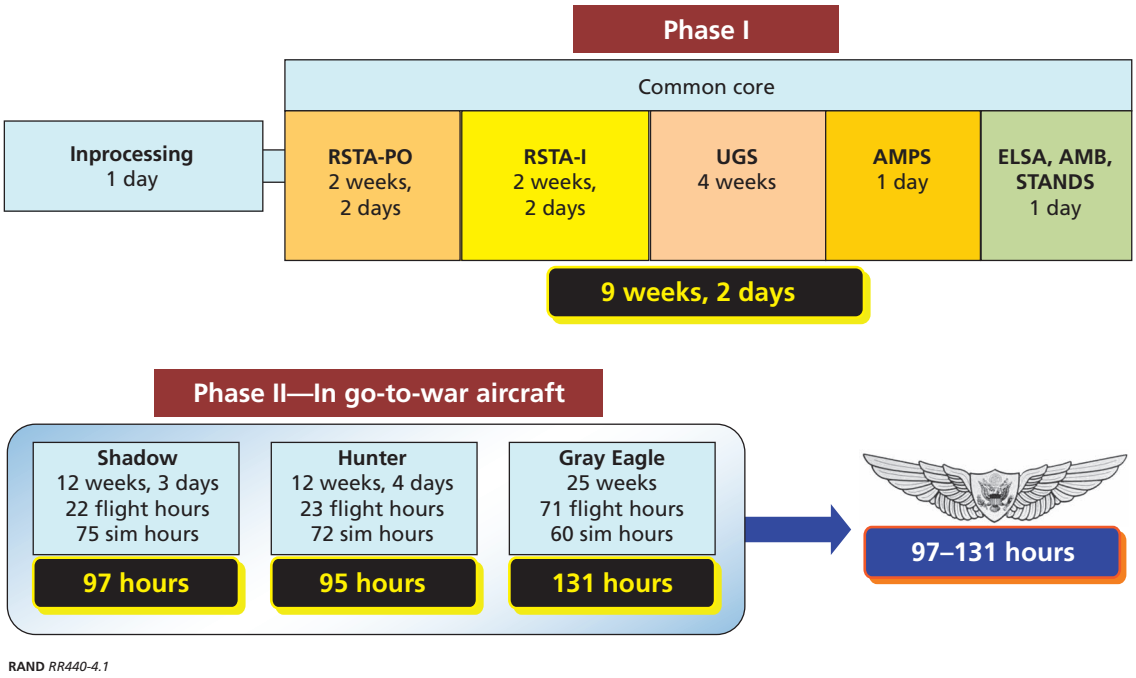
Ground Forces

Ground force operations of the Army and Marine Corps, even at low echelons, can be highly complex, and the complexity increases significantly at higher echelons. Commanders at higher echelons not only have to coordinate and use the information and capabilities subordinate units provide but also have to manage and integrate information and capabilities from a widening variety of other sources available to them. Adding the integration of UAS capabilities into the operational command further increases its complexity and thus the complexity of associated training management processes. Evidence from both training exercises and actual operations in combat theaters shows that, when properly managed, UASs provide significant new capabilities that commanders at every echelon can effectively employ. UASs truly have the potential to be force multipliers—but more so when employed by users fully competent in integrating their capabilities with those of the rest of the force and its supporting elements.

As shown in the training framework presented in Chapter Three, the proper integration of UASs to create combat capability starts with the training of UAS operators and support personnel and progresses through the integration of UAS operations with supported forces.

Training for Operators and Support Personnel

In general, the RAND team found that qualification training in the Army and Marine Corps for designated UAS-specific MOS is well established. In the Army, positions are filled by enlisted soldiers. The ranks of operators typically range from private first class to master sergeant (E-3 to E-8). The Marine Corps is organized much like the Air Force, with a UA commander who is a company grade, qualified aviator or aviation C2 officer on his or her second or third tour (O-3/O-4) and a mission payload operator (MPO) who is typically a corporal through master sergeant (E-3 to E-8).



Army Air Vehicle and Sensor Operators for Hunter, Gray Eagle, and Shadow UASs

Training for Army UAS operators—pilots and payload operators—is carried out in two phases: The first, at Fort Huachuca, consists of a common core course for all operators of UASs not launched by hand.[2] This phase lasts nine weeks and two days and has five sections. (See Figures 4.1 and 4.2.)

[2] The 2nd Battalion, 13th Aviation Regiment, which was previously called the Unmanned Aircraft Systems Training Battalion, conducts the training. See Appendix D for RAND's "military value analysis of training bases" assessment of training at Fort Huachuca, Arizona.

4599 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Figure 4.1
Army UAS Air Vehicle Operator and APO Training Pipeline

After completing Phase I, the operators continue to Phase II. This section is unique for each airframe and consists of both simulation and flight hours. It typically takes 12.5 weeks for Shadow and Hunter classes to finish and 25 weeks for Gray Eagle classes. After completing Phase II, the UAS operators earn their wings.

Maintenance for Hunter, Gray Eagle, and Shadow UASs

The Army UAS maintainers take the MOS 15E Repairer course from the 2nd Battalion, 13th Aviation Regiment (see Figure 4.3). As shown in Figure 4.4, the course lasts 17 weeks, and a new class of up to 16 students starts every two weeks. After completion, 15E personnel are qualified to maintain the Shadow. Maintainers must take additional training to earn additional skill identifiers and thus qualify to maintain the Hunter and Gray Eagle. The additional training takes ten weeks for Hunter and 18 weeks for Gray Eagle.

Army Raven Operators

Without a dedicated MOS, the development and maintenance of Raven operators is a unit personnel and training management issue. Assignment as a Raven operator is an additional duty. In the past, this has meant that many units did not have the required Raven-qualified personnel to employ the systems properly. The Army is well aware of this problem and, short of creating a dedicated MOS, has recently initiated a program to deal with the Raven training problem. The Army Maneuver Center of Excellence at Fort Benning manages a certification course designed to qualify selected soldiers as small UAS (SUAS) master trainers capable of conducting initial qualification training (IQT) and certification of new operators at home stations throughout the Army. This train-the-trainer course focuses on how to teach and manage an aircrew training program at home base and how to assist small-unit commanders in evaluat-

ing academic and flight instruction and managing SUAS accident prevention.[3] It is envisioned that new master trainers returning to their home stations will be able to develop and maintain

[3] The 15-day course includes classroom and hands-on training, with instruction on reporting procedures, fundamentals of instruction, semiannual evaluations, and familiarization with Raven A and B and digital downlink systems. At the conclusion of the training program, graduates should have the ability to evaluate and certify operators. See U.S. Army Maneuver Center of Excellence, undated.

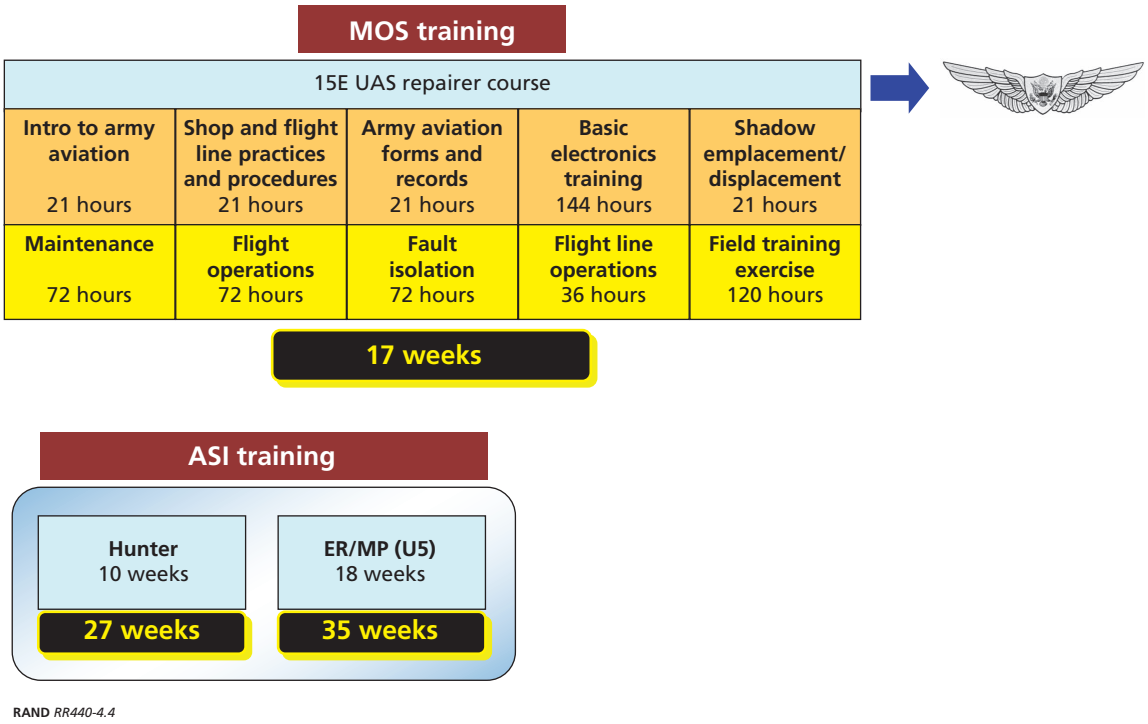
a sufficient number of operators within their units and manage a tracking program to ensure that their units have the required number of certified Raven operators.

Marine Corps Unmanned Aircraft Commanders—Pilots



Training begins with the Unmanned Aircraft Commander course, which last two weeks and is taught by the U.S. Army at Fort Huachuca. Career-level training takes place at the squadron level. Marine Aviation Weapons and Tactics Squadron 1, at Marine Corps Air Station Yuma, Arizona, provides advanced training (the Weapons and Tactics Instructor course).

Air Vehicle Operators and Mission Payload Operators

Training for air vehicle operators (AVOs) and MPOs is accomplished jointly with the U.S. Army at Fort Huachuca. USMC operators take the nine-week common course and the 12-week Shadow course. Career-level training takes place at the squadron level. Marine Aviation Weapons and Tactics Squadron 1 provides advanced training.

4602 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Figure 4.4

Operational Training[4]

Larger UASs have dedicated MOS training, so operators and maintenance personnel arrive at home station having completed their IQT. To maintain their proficiency and certification, crews must log a minimum number of flying hours. The Army's Gray Eagle UAS has its own simulator capability built into the operating hardware. Currently, the Army's requirement is for 4.5 live flying hours per crew per month for the Shadow UAS. The Army has had difficulty maintaining sufficient numbers of Raven-qualified SUAS operators, in part because units do not always do well in tracking their qualified operators, maintaining their proficiency through hands-on work, and providing for their timely replacement when they move on. Discussions with Army trainers indicate that, despite the demands of deploying units and sustaining combat operations in Afghanistan, Army units are doing better at maintaining Shadow qualification. Nevertheless, not all units have been able to maintain high Shadow qualification rates: Some units arrive at the NTC with one-half or fewer of their operators qualified.

For these systems, the critical issue for the future will be securing enough flying time for UAS crews to train with ground forces. Marine Corps experience offers a good illustration of this issue. The Marine Corps has based Shadow squadrons at the MCAGCC, where there is adequate restricted airspace both to maintain crew proficiency and to fly in support of ground forces. However, both the ground trainers and squadron personnel the RAND team interviewed reported having to start what was essentially remedial training because the ground

[4] Joint Publication 1-02 defines *operational training* as "training that develops, maintains, or improves the operational readiness of individuals or units" (JP 1-02, 2013).

4603 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

forces were not adequately trained at home station to integrate UAS capabilities into their operations. These students generally could not progress to the level of proficiency desired.

The foregoing suggests the biggest challenge in developing and implementing a training strategy for UASs is gaining and maintaining proficiency on the part of end users—the leaders and staff members who will integrate UAS capabilities into their operations.[5] Ground units that undertake joint training at CTCs are often unprepared to use organic and nonorganic UASs effectively, and thus tend to develop battle plans that underutilize them.[6] Further, their intelligence and operations staffs sometimes find themselves at cross purposes over employment of UASs, an issue that could be better dealt with during home-station training.

Despite all this, discussions with operators, users, trainers, and training managers suggest that properly employed UASs consistently prove to be valuable combat multipliers. One example was an Army unit training at the NTC, which had successfully employed its UASs as part of a manned-unmanned team. In this instance, the UAS had acted as a scout and observer as manned attack helicopters delivered fires on selected targets, all in support of a ground maneuver unit. Another battalion well versed in the myriad tasks associated with employing Shadows—communication of commander's intent and concept, priority and time sensitivity of information requirements, targeting priorities, use of the communications relay package, to list just a few—was far more successful in employing the Shadows supporting it than another unit was. In the latter unit, the UAS platoon was simply given "areas to look at," without specific guidance on what to look for, e.g., named areas of interest and targeted areas of interest. Interviewees told the RAND team that many UAS operators do not get enough opportunity to interact with either crews of manned aircraft or the elements of ground units—commanders and operations and intelligence sections—that they will support.

The latter problem, ground units' lack of experience in employing UASs, is all too common. It is also true for the USMC, whose units face considerable limitations on using UASs at their home stations or local training events.[7] Marine ground force units are thus typically not well versed in employment of UASs when they arrive at Twentynine Palms. Although they learn while there, many are still not fully capable when they deploy.[8]

Improvements in Facilities and Basing for UASs Will Improve Training Integration

To date, the Army has had reasonable opportunity to train at home station, and current programs to increase UAS facilities will appreciably add to this. Table 4.1 summarizes responses the U.S. Army Training and Doctrine Command (TRADOC) received from active, National Guard, and reserve bases in November 2012 concerning the availability of restricted airspace and resulting limitations on UAS operations stemming from lack of availability. The responses

---

[5] We refer to anyone who could benefit from the information a UAS provides as an *end user*. The MTTP calls end users *supported units*.

[6] *Organic* assets are ones owned by a unit, and *nonorganic* assets are ones that the commander of a unit does not own and thus does not have full control over.

[7] Recall that the Marines' Shadow squadrons are based at Twentynine Palms when not deployed.

[8] This brings up the question of whether we should expect units to continue learning sound tactics and procedures while they are deployed. They should, of course. The issue is how much; officials we have consulted have given us the sense that many units are still on the steep part of the learning curve when they leave the MCGACC. These units would be more operationally effective sooner in their deployments if they could be better trained to integrate UAS capabilities before they deploy.

4604 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

indicate that, in many cases, relatively minor military construction projects are all that is necessary to expand training opportunities at home stations. In most locations, additional beddown facilities will allow better use of existing restricted airspace to facilitate live training. In a few cases, however, the proximity of training areas to the Federal Aviation Administration (FAA)–controlled National Airspace System (NAS) remains a problem. The summary in Table 4.1 provides a snapshot of the kinds of issues that have already been raised and will have to be revisited at some point because of the ongoing pressure to reduce defense budgets.

Table 4.1
Select Summary of Army UAS Installation Survey as of November 21, 2012

Base/Commands	Answer To Question E: Does Available Restricted Airspace Affect/Limit UAS Operations at Your Installation?	Answer To Question J: What Solutions Would You Recommend for Unsolved Issues?	Shadow Strips Planned for FY 2013
Alaska (Forts Wainwright and Richardson)	No.	We have been able to accommodate all down range requests. However, the hangars are nonstandard and need to be evaluated for suitability as the Shadow and Gray Eagle platforms evolve.	
Fort A. P. Hill	During landings the tactical approach landing system orbit is outside the restricted airspace.		Yes
Fort Bliss	Our special use airspace is bisected by a major highway which requires a COA.	Yes, a Shadow Strip in the SUA.	Yes
Fort Bragg	Yes.	Yes. Primarily commercial power and hardened maintenance facilities. Temporary solutions are power generation equipment and tentage.	Yes
Fort Carson	Yes, limited by the volume of manned/unmanned platforms operating within the airspace.	Yes, requests for designated UAS facilities and airstrip for launches and recovery. Funding established to build a multiple platoon facility for UAS units.	Yes
Fort Drum	No.	No. We have no unresolved UAS issues.	Yes
Fort Hood	Not currently.		
Fort Knox	No.	Yes; the construction of a tactical UAS field support structure (build it).	
Hawaii	Yes, we have requested to use the Kahuku and East Ranges for flights but due to FAA restrictions, we cannot fly UAS/SUAS platforms in these airspaces.	No. We need more airspace to train in. Our current location is becoming less and less amicable to flight conditions due to public demands on land. In 2010, plans were drawn up to provide for a permanent UAS facility at Wheeler Airfield, but they were cancelled due to program funding.	

4605 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Table 4.1—Continued

Base/Commands	Answer To Question E: Does Available Restricted Airspace Affect/Limit UAS Operations at Your Installation?	Answer To Question J: What Solutions Would You Recommend for Unsolved Issues?	Shadow Strips Planned for FY 2013
Fort Lewis (Joint Base Lewis-McChord [JBLM])	1. Yakima Training Center (YTC): No not an issue. 2. JBLM: Yes, both the limited restricted airspace and the large number of installation units requiring restricted airspace, challenge UAS/SUAS operations.	1. YTC: Shadow Training Facility 2. JBLM: Construction of a second Shadow landing strip. 3. JBLM: Construction of any type of permanent, securable facility alongside the existing Shadow landing strip (location is outside JBLM's guarded area). 4. JBLM: Shadow Training Facility or TEMF.	
Fort Riley	Not currently. (See response to Q h & i.)	Nothing to comment on.	Yes
Fort Stewart	Not significantly. However, reductions in air traffic control manning are a concern. There are currently no significant restricted airspace challenges negatively affecting UAS operations.	Funding, we have a plan and the requisite site approvals, we just need funding support. We need the funding ($701,000) now for our third Shadow platoon hangar; we have the design ready to go and at contracting.	
USAREUR	Yes. 173rd Shadow out of Italy is currently based in Bamberg due to no restricted airspace to fly in Italy. Currently fly in restricted airspace in Grafenwoehr/Vilseck Training Areas.		
Camp Atterbury	No, both UAS facilities are within restricted airspace.		
Fort Chaffee	No restricted airspace limitations to TUAS flight operations.		Yes
Orchard Range	Yes, UAS operations are limited to using R-3203.	Fixed support facilities UAS operations. Facilities will be in Range Complex Management Plan.	
Fort Pickett	No, we have one of the largest SUAs in the Midatlantic.		
Camp Ripley	No, the restricted airspace at Camp Ripley (R-4301) provides enough area to conduct training for the current systems.	Yes. The current tactical strip will be removed for the construction of a MPTR. UAS commanders have requested a tactical strip for replacement that includes hard-stand buildings and electrical power. The Combat Readiness Training Center currently has a location selected that has power in close proximity to the existing tactical strip. Camp Ripley is one of the sites to receive $730,000 for construction of a UAS strip in the down-range area in FY 2013.	Yes
Camp Roberts	No.	Funding.	Yes

4606 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Table 4.1—Continued

Base/Commands	Answer To Question E: Does Available Restricted Airspace Affect/Limit UAS Operations at Your Installation?	Answer To Question J: What Solutions Would You Recommend for Unsolved Issues?	Shadow Strips Planned for FY 2013
Fort Dix	Yes.	We have accommodated all downrange requests. However, the size restriction of the UAS in R-5001 limits operation of large UAS operations.	
Fort Hunter-Liggett	No, we use R-2513 airspace.	None.	
Fort McCoy	Yes, Current coutilization of Young Air Assault Ship, a 6,250-ft. C-17/C-130 landing strip in R-6901 B. The UAS operations at this landing strip affect Sparta/ Fort McCoy airport operations.	Yes. Hangers for Shadows and permanent facilities with commercial power, and asphalt. Standard design and funding required.	
Fort Campbell	Fort Campbell currently has two approved sites for Shadow Flight operation; both are located among numerous field artillery firing points, which requires de-confliction during launches and landings because the firing points have to check fire. As a result, UAS flight training is significantly reduced. However, an additional UAS strip is being constructed to alleviate this problem.	Yes. Permanent facilities with commercial power and utilities.	

SOURCE: Installation UAS survey responses from TRADOC Capability Manager—Live, as of November 21, 2012.

Key Areas of Concern

As the war in Afghanistan draws to a close, the services must pay close attention not only to the training of UAS crews and support personnel but also to the routine exercise of these systems as part of combined arms training at home station and at the CTCs. This will require attention to a number of issues.

Beddown and Related Support Facilities

To facilitate the efforts described above, DoD should support current and future programs to develop ranges and beddown and support facilities similar to those in the Army's current programs. The Army has been implementing a robust program to establish Shadow beddown facilities—runways, shelters, and attendant support structures—on many of its installations, both active and National Guard. This will enable more opportunities both for UAS operators and for end users.

Airspace Considerations

As the responses reported in Table 4.1 suggest, the unique limitations of UASs pertaining to operations in the NAS can make integration into home station training difficult. Currently, UASs can operate only in restricted military airspace or, in the NAS, with certificates of authorization (COAs) from the FAA. In some cases, it should be possible to increase UAS training with ground forces (and with collocated manned aircraft units) without impinging in any significant way on the NAS. Although this will certainly require better coordination of restricted airspace at individual installations, better availability of restricted airspace will make better

4607 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

access to the NAS less of a key element in supporting training strategies, at least as they pertain to home-station or local training of ground forces. However, less-cumbersome procedures for NAS access will, among other things, facilitate opportunities for units to employ larger UASs, such as Gray Eagle, Predator, and Reaper, in home-station training events.[9]

Air Force

The Army and the Air Force have significantly different concepts for employment of UASs. The Air Force uses a remote split operations concept to employ its UASs. Under this approach, the Air Force flies UASs from home station using satellite or other relay links. It maintains only small deployed footprints at consolidated operating locations to launch, recover, and maintain the aircraft.[10] This approach enables the deployment of the vast majority of its systems, yet the majority of the personnel who operate Air Force UASs do so from home station and require no reconstitution following deployments. By using remote split operations, 85 percent of the Air Force's UASs would be forward deployed for combat operations. The remaining 15 percent would support training at each operational base. The Air Force employment concept, however, does not facilitate integrated operations with Army tactical-level units during training at Army home stations. Once deployed, Army brigades, battalions, and SOF must learn to work with Air Force TACPs to coordinate UAS operations.

Training for Pilots, Operators, and Support Personnel

The Air Force uses a crew of one pilot and one sensor operator to man each UAS mission.[11] The pilots are officers and are either rated pilots who graduated from undergraduate pilot training or UAS-only pilots who graduated from a new program called undergraduate remotely piloted aircraft training.[12] UAS-only pilots have the 18X Air Force Specialty Code (AFSC) and will be discussed in more detail later. Following the structure of the training pipelines for other platforms, the training is broken into three phases: IQT, mission qualification training (MQT), and crew mission ready training. Air Education and Training Command conducts IQT and MQT, with the latter taking place in a formal training unit (FTU).

[9] In some cases, basing for the larger systems, especially Gray Eagle, will be contiguous with the training areas in which they are needed; Fort Hood, Texas, is an example. But this will not always be possible. The larger systems require longer and better runways and larger and more-sophisticated beddown and support facilities. It may be more cost-effective to move these UASs to support training where they are needed, rather than establishing beddown facilities in a large number of additional locations.

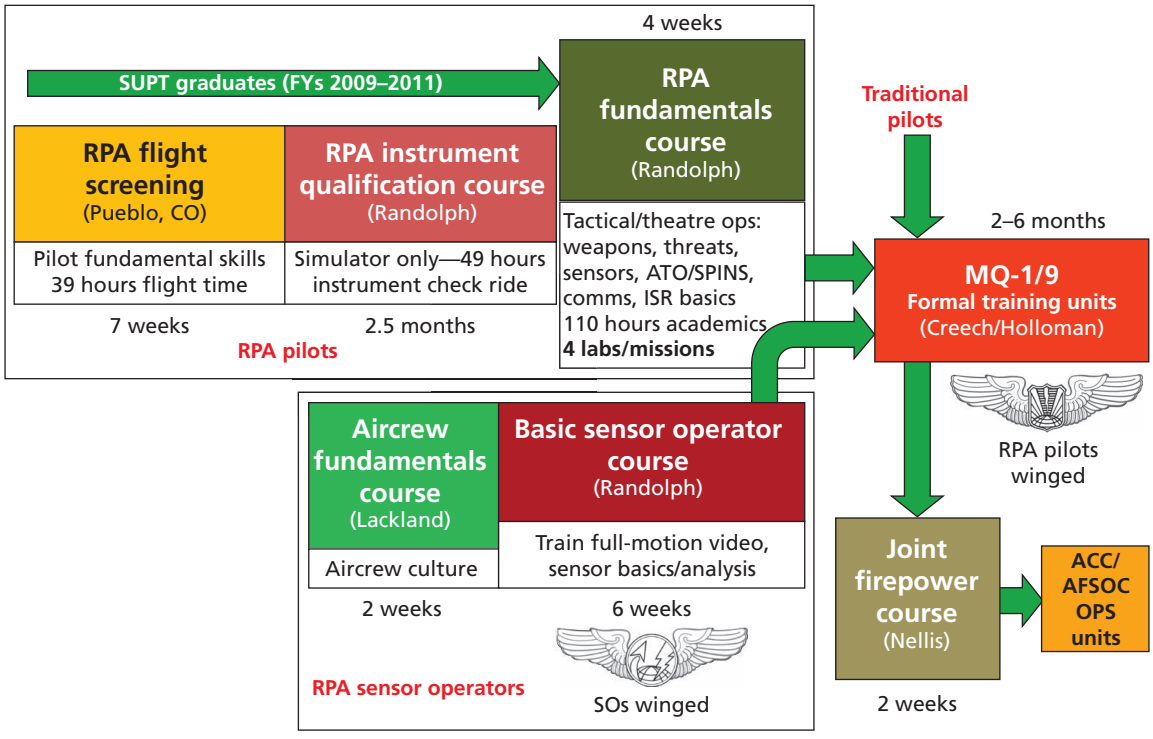
[10] The 432nd Wing at Creech AFB operates MQ-1 Predators and MQ-9 Reapers from seven forward bases overseas. Maintainers at forward bases serve four-month rotations in theater.

[11] Many more people are involved in RPA operations, including the mission intelligence commander. Also, there is a weapon school course for advanced training of RPA operations. For this research, we were primarily interested in the initial training of pilots and sensor operators.

[12] Some Air Force navigators who had commercial instrument qualifications have been allowed to train as pilots for the RQ-4. This avenue for sourcing RQ-4 pilots closed in spring 2011.

4608 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Pilots



Reaper and Predator

In response to the need to reach and sustain the manpower to fulfill Reaper and Predator requirements, the Air Force initiated a new program to produce RPA pilots.[13] Currently, Reaper training takes place at Hancock Field Air National Guard Base in Syracuse, and Predator training takes place at Holloman AFB. New RPA pilots have attained the foundational skills to conduct RPA missions and are qualified to operate in the NAS or International Civilian Aviation Organization airspace. Figure 4.5 outlines the training pipeline. Figure 4.6 shows the UASs.

Global Hawk

Currently, most Global Hawk pilots are traditional Air Force pilots who volunteered for a tour in the Global Hawk (see Figure 4.7), a majority of whom are qualified to fly multiengine transport aircraft. Prior to 2011, navigators who also had commercial pilot licenses and had completed commercial instrument qualifications were allowed to become Global Hawk pilots; however, the Air Force has not decided whether to retain navigators who are currently Global Hawk pilots in the community or return them to navigator duties. The third source of Global Hawk pilots is the 18X career field, UAS-only pilots who have graduated from undergraduate remotely piloted aircraft training. After finishing the three preparatory courses, candidate Global Hawk pilots head to the RQ-4 FTU, the 1st Reconnaissance Squadron at Beale AFB.

Figure 4.5
Air Force UAS Pilot and Sensor Operator Pipeline

RAND *RR440-4.5*

[13] The Air Force uses the term *RPA* to refer to unmanned aircraft systems. The accepted joint terminology is *UAS*.

RAND *RR440-4.7*

Sensor Operators

Reaper and Predator

Enlisted sensor operators for Reaper and Predator are either trained into a new career field or cross-trained from another AFSC (1U00X). After graduating from the Air Force's basic training or being reclassified, they attend a two-week course at Lackland AFB, Texas, with other aircrew AFSCs. Then they go to Randolph AFB, Texas, for a six-week basic sensor operator course. After completion, they go to the appropriate FTU for the system they will be flying.

Global Hawk

Sensor operators for the Global Hawk are trained differently from those for other UASs. Sensor operators for the Global Hawk come from the intelligence imagery analyst career field (1N1XXs). They receive MQT at Beale AFB, where they learn to use the Global Hawk system. After one tour as sensor operators (approximately three years), they move on to other imagery analyst assignments; therefore, it is difficult to maintain expert sensor operators for the Global Hawk.

Maintenance

Training for those who maintain Air Force UASs takes place at three locations.[14] The fundamentals are taught at the maintenance schoolhouse at Sheppard AFB, Texas. Initial skills training and advanced skills training take place at the unit.

[14] Contractors provide certain UAS maintenance, for example, depot-level maintenance.

4611 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Operational Training

Given the emphasis on current operations and the Air Force's remote split operations concept for employing UASs, few opportunities exist to support ground troops either during home-station or CTC training. In general, with a few limited exceptions, Air Force UAS crews do not train in exercises or other training events in CONUS and do not support training in CONUS of Army or Marine Corps units at either their home stations or at the CTCs. Air Force UAS crews do conduct operational missions in theater, and these missions frequently are the chief or even the only way deployed Army and Marine Corps units get an opportunity to work directly with Air Force UAS crews. Thus, most elements of the UAS force in theater often have no experience working together before they have to do so in combat operations.

The result of not working with ground troops either at home station or the CTC is that ground units generally do not integrate Air Force UAS capabilities into their planning. RAND's conversations with the training community, including trainers at the NTC, as well as what officials told the GAO, confirmed that the

> effective integration of UAS in training exercises, like the integration of other types of joint air assets, depends on the priority that ground units place on developing training objectives that require the participation of joint air assets and their ability to plan for the use of these assets in the exercise. … [As a result], Army combat brigades often focus UAS training objectives during exercises on integrating their Shadow UAS and do not emphasize planning for and employing Air Force UAS.[15]

---

[15] Independent RAND team visits also confirmed what the Air Force told the GAO, that

> unmanned aircraft are deployed to support overseas operations except for those that are supporting the initial training of UAS personnel or the testing of aircraft." These officials [from the 432 Wing] stated that in the event that additional aircraft were made available, the wing's personnel levels are insufficient to support additional training events because the unit does not have adequate personnel to support projected operational commitments and greater numbers of training exercises. Second, Army and Air Force officials told us that when Air Force UASs are at the training center, these aircraft are not always available to support ground unit training because a considerable portion of the UAS flight time is dedicated to accomplishing Air Force crewmember training tasks. Officials told us that the Army and Air Force have reached an informal agreement to allot about half of the time that an Air Force UAS is flying at the training center to support Army ground unit training objectives and the other half to accomplish Air Force training tasks. Air Force officials pointed out that although they try to align their crewmember training syllabi with ground unit training objectives at the National Training Center, training new personnel to operate these aircraft is their priority. Third, UASs may not be available during certain hours to support ground unit training, which during exercises goes on 24 hours a day. For example, Predator UASs from the California Air National Guard are available to support ground units only during daylight hours. To travel to the training center, these aircraft must pass through segments of national airspace that are not restricted for DOD's use and therefore must rely on a ground-based observer or on chase aircraft to follow them to and from the training center. Because of this reliance on ground or airborne observers, flights to and from the training center must be accomplished during daylight hours and are necessarily more expensive as well.
>
> As a result of the limited number of unmanned Air Force assets that are available to support ground unit training at the National Training Center and the Joint Readiness Training Center, Army ground units conducting training exercises have frequently relied on manned aircraft to replicate the capabilities of the Air Force's Predator and Reaper UAS. Officials told us that the use of manned aircraft in this role permits ground units to practice the process to request and integrate the capabilities provided by Air Force UASs in joint operations. However, this practice is not optimal, as the manned aircraft do not replicate all of the capabilities of the Predator and Reaper aircraft, such as longer dwell times.

GAO, 2010a, p. 26.

4612 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Key Areas of Concern

We note above that, as the war in Afghanistan draws to a close, the services must pay close attention not only to the training of UAS crews and support personnel but also to routinely including these systems in combined arms training at home station and at the CTCs. This will require attention to a number of issues.

Beddown and Related Support Facilities

Discussions with officers of the 432d Wing suggest an Air Force future much like the past: flying in support of COCOM requirements worldwide. If this comes about, there will continue to be limited opportunities for the Air Force to support Army or Marine Corps training at the home station or CTCs. Alternatively, if providing such training becomes a priority, the Air Force's current basing and beddown posture will become a problem.

Airspace Considerations

The unique limitations of UASs pertaining to operations in the NAS make integration into home-station training difficult. Currently, UASs can operate only in restricted military airspace or, in the NAS, with COAs from the FAA. These COAs can often be prohibitive to participating in joint training. For example, the MQ-1 FTU from March ARB tried to participate in training with the Marines at Twentynine Palms. Unfortunately, the COA requires a manned chase plane and, given the geography, the contracted chase plane cannot fly the shortest route. The only option is to fly through the restricted airspace between Fort Irwin and Twentynine Palms, which is prohibitively long because the COA permits operations only during daylight hours. These limitations restrict where UASs can be used because an installation must have access to a significant amount of restricted airspace. Other limitations include the basing expense of sprinkling UASs across the country to embed with Army or Marine units at home station.

Several different possibilities could be considered to help increase joint training opportunities. The Air Force could consider the location of Army hubs when choosing where to base its UAS fleet. A location that is near Army maneuver elements might make airspace access less of a restriction or at least make COAs more practical. Proximity might provide more opportunities for training UAS integration throughout the entire mission planning process.

Alternatively, the Air Force could permanently leave a small number of UASs at a training location and remotely operate these from Holloman AFB, Creech AFB, or other locations. These systems are designed to employ remote split operations, in which the crew operating the platform need not be colocated with the platform. The various Air Force units could get flying time by cycling through these dedicated aircraft. This option would provide Air Force crews—including launch and recovery crews—practice integrating with ground forces and would simultaneously support the ground forces' need for integrated training. This plan would also reduce the issue of airspace access because the aircraft would be located within the restricted airspace in which they would be used or at an auxiliary airfield close enough that a COA would be practical.

A promising development that enhances UAS training is the advancement of ground-based sense-and-avoid (GBSAA) and airborne sense-and-avoid (ABSAA) technologies. These may open up regions of civil airspace for properly equipped UASs to operate safely in accordance with the FAA's mandate to "do no harm" without requiring FAA issuance of COAs. In particular, GBSAA has recently completed a series of successful demonstrations, and the

4613 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Army is planning to GBSAA equip a number of its UAS training bases to extend their current military airspace with adjoining civil airspace to increase UAS training capacity by 2015. The Army is the lead for the development of GBSAA, but GBSAA has been designed for the use of all the services. Each service, like the Army, would use one of its existing ground based radars in implementing GBSAA. ABSAA's implementation uses UAS-borne sensors and electronics, including those not currently on UASs. Current development of all-weather ABSAA that could operate without FAA COAs is restricted to Global Hawk, with plans to scale down to Reaper. ABSAA availability is not known at this time but will be some years after GBSAA becomes available.

Navy

Relative to the Air Force and Army, the Navy has had limited experience with UASs. To date, Navy ships have employed the Scan Eagle, a non–program of record UAS, fielded through a rapid-acquisition program (see Chapter Two). Scan Eagles are flown from frigates. The Navy has also operated BAMS-D,[16] which is scheduled to be replaced by the MQ-4C, Triton.[17] The Navy is acquiring the Fire Scout (MQ-8B). While we limited most of our study effort to the period through FY 2012, the Navy's most recent experience is the best example of the evolution of UASs and their implications for operational capabilities. In early May 2013, the Navy launched an X-47B experimental drone from the nuclear powered aircraft carrier USS *George H.W. Bush* as it operated off the coast of Virginia (Vergakis, 2013). This launch represented the latest step in introducing a disruptive technology into the operating forces and helped mark a paradigm shift in warfare because this particular UAS is capable of autonomous flight.

The Navy's approaches to integrating UASs and to training and developing UAS operators differ significantly from those of the Army and Air Force. Generally, Navy UASs are being incorporated into existing fleet aviation units and organizations, and the personnel who will operate them are, to a large extent, the same personnel who will operate traditional aircraft assigned to these organizations. In this way, the Navy is addressing several problems often seen when disruptive technologies are introduced. The Navy approach has emphasized the complementarity of the systems, rather than pitting the new technology and its proponents against the old technology and its proponents. In addition, the Navy will reduce cost by capitalizing

[16] While the Air Force has conducted Global Hawk UAS operations since 2001, the Navy has just recently pursued using the system. The Navy purchased Global Hawk airframes from the Air Force and is using them to test operational concepts and technologies. The aim for the Global Hawk maritime demonstration program, BAMS-D, is to better understand maritime surveillance with UASs that fly at high altitude. The goal is to improve the fleet's operational understanding of the battlespace, and the Navy deployed BAMS-D in 2009.

[17] The Navy's BAMS UAS (MQ-4C), now called Triton, is a persistent maritime intelligence, surveillance, and reconnaissance system. As a persistent airborne asset, Triton's sensors will support increased situational awareness for naval forces. The imagery and data provided by the airframe's sensors will be directly available within federated networks, allowing Navy, joint, allied, and coalition exploitation centers to use MQ-4C UAS data.

While the Navy is currently operating only BAMS-D (in FY 2012), it plans to purchase a total of 68 Triton MQ-4C UAS airframes from FY 2014 through FY 2026. This acquisition plan will increase deployment of BAMS to operational commanders throughout the world. The current concept of operations includes plans for the Navy to operate Triton UASs in five separate geographic locations. These operations would provide continuous maritime surveillance, with persistent ISR support 24 hours a day, seven days a week, out to ranges of 2,000 nautical miles from the deployed location. (Derived from Department of the Navy, 2010.)

4614 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

on investments already made in personnel aviation training. For example, the Fire Scout UAS will be embedded in Navy H-60 squadrons.[18] This enables taking advantage of H-60 pilots' training and experience, because they will also pilot the Fire Scout. The flying skills of the H-60 pilot are utilized for both airframes and minimize the potentially disruptive effects of this new technology. Similarly, Triton, the follow-on to BAMS-D, is intended to complement Navy P-3/8 aircraft with its long loitering capability and sensors. The Navy plans to have P-3/8 officers both be in tactical command of the UAS and pilot the Triton UAS. These officers will first serve and qualify in the P-3/8 aircraft, rotate to a UAS training unit, then assume duties in a UAS squadron. The Triton UAS capabilities complement the capabilities of the P-8 aircraft. The training construct the Navy is pursuing will capitalize, complement, and exploit the capabilities of both aircraft and the personnel assigned to them.

Training for Operators and Support Personnel

Scan Eagle

Qualification training for personnel directly associated with UAS operations is not yet well established for the Navy. Currently, contractors operate the Scan Eagle UAS. (See Figure 4.8.)

Fire Scout

The Navy will have two approaches for Fire Scout operator training—one for littoral combat ship (LCS) employment and another for SOF support. The majority of Fire Scouts will be flown from the LCS. (See Figure 4.8.)

Littoral Combat Ship Employment

The aviation detachment that will deploy with the LCS will consist of one H-60R helicopter and two Fire Scouts and will have 23 assigned personnel. The training these personnel will need is similar to that for deploying with H-60 detachments on guided missile destroyers today (normally, two H-60 helicopters deploy with a guided missile destroyer). In the future, ships will deploy with a mix of H-60s, and Fire Scout and aviation detachment personnel will fly both aircraft depending on mission requirements.

The skills needed to operate and maintain the Fire Scout are complementary to those needed for the H-60. The operators and maintainers of Fire Scout will be the same as for the H-60, with some additional training on the Fire Scout. An H-60 fleet replacement squadron's (FRS's) Fire Scout fleet introduction team will provide this training to the AVOs and MPOs en route. The AVO course for H-60 pilots lasts five weeks. This initial and all sustainment training for the Fire Scout will be conducted via simulator.

Fire Scout Support for Special Operations Forces

The Navy is establishing dedicated units to support SOF, rather than integrating Fire Scout into existing units. The first of these units, Unmanned Helicopter Reconnaissance Squadron One, will be both a training and an operational squadron. The Navy's plan is to organize each such squadron to have nine detachments, each consisting of three Fire Scout airframes, seven to eight AVOs, eight MPOs, and 16 maintenance and support personnel. The Fire Scouts that will be flown off LCSs will be piloted by commissioned officers. The Fire Scouts supporting

[18] The Fire Scout will greatly contribute to increased mission readiness and response by conducting persistent ISR operations immediately around seaborne task forces, as well as over the horizon. The persistence, range, sensors, and data sharing of UASs extend the ISR reach of Navy ships and increase situational awareness.

SOURCE: DoD.

RAND *RR440-4.8*

4616 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

SOF units will be piloted by enlisted AVOs. Initially, these AVOs will be air warfare operators who have completed tours as MPOs with an LCS Fire Scout.

Fire Scout Maintainers

The Fire Scout maintainers consist of four Navy specialties. Enlisted aviation machinist mates and aviation structural mechanics will take the mechanical course for LCS Fire Scout. Enlisted aviation electronics technicians and aviation electrician's mates will take an electronic technical course for LCS Fire Scout. The maintenance and support skills needed for the Fire Scout are complementary skills for Navy enlisted technicians.

Triton

Operator Training

The MQ-4C Triton UAS is composed of several systems: the airframe; a suite of mission payloads; communications systems; a mission control system (MCS) used for mission planning, control, and execution; and a support system. The Triton UAS will be deployed as an adjunct system to P-3/8 squadrons. The MCS will be based at a main operating base in CONUS, and BAMS maintenance and launch and recovery operations will take place at a forward location.

The Triton watch organization will consist of a mission commander (P-8 naval flight officer),[19] one AVO (officer, P-8 pilot), and two mission payload (enlisted) air warfare operators. Training plans for the Triton watch organization are being developed, and the initial operating capability of Triton will be in FY 2016. The Navy plans to use P-3/8 pilots as tactical coordinators and AVOs on the Triton. Future aviators will first go through flight school, earn wings on the P-3/8 aircraft, then perform an initial operational tour on the P-3/8.[20] After that, aviators will rotate to the FRS for training on Triton before reporting to their squadrons. Designated FRS for BAMS is Patrol Squadron 30 (VP-30), located at Naval Air Station Jacksonville, Florida. FRS training provides initial and refresher qualification training for personnel who will be assigned to Triton units.

Maintenance personnel and the pilot who launches and recovers the airframe are located at the forward operating base. The Navy plans to rotate personnel through the forward base every several months.

A simulation training capability will be built into the MCS. Initial Navy manning plans indicate that there will be eight to ten crews per squadron. The crews will be flying real missions that will sustain their proficiency. Triton UASs are flown via point and click; there is no stick and rudder. VP-30 is developing the tailored Naval Air Training and Operating Procedures Standardization requirements for the Triton; the final training and readiness manual for Triton is due in 2013.

Maintenance Training

The Triton airframe, engines, and associated equipment are different from the P-3/8; one is a UAS and the other a manned aircraft. Separate training will thus be necessary. When the

[19] The mission control officer is a naval flight officer who is responsible for the mission planning and the overall tactical employment of the airframe. The AVO is a naval aviator, responsible for flight planning and safety of flight, and is the pilot in command of the airframe. The MPOs are enlisted air warfare operators, responsible for the operation and employment of the sensors and the detection and analysis of targets.

[20] The notional pilot training track for P-3/8 pilots is (1) attend and graduate from flight school, (2) attend FRS for P-8 training, and (3) conduct an operational P-8 squadron tour.

4617 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Triton UAS is introduced into the fleet, the Chief of Naval Air Technical Training will stand up a technical school to train enlisted personnel to perform Triton maintenance.

Operational Training

BAMS/Triton

The P-8A's missions overlap with those of Triton. The missions the two have in common include maintaining the maritime common operational picture and the classification, identification, detection, and tracking of surface units. The P-8A, however, has missions that the Triton does not perform (e.g., antisubmarine warfare) and vice versa. However, the increased utilization and cross training of P-8A and Triton crews over time can and is expected to increase understanding and employment of these systems in support of the warfighter.

While the Navy was operating only BAMS-D in FY 2012,[21] the Navy has plans to purchase a total of 68 Triton MQ-4Cs UAS airframes from FY 2014 through FY 2026. This acquisition plan will increase deployment of Triton UAS to operational commanders throughout the world. The current concept of operations includes plans for the Navy to operate Triton UAS in five geographic locations. These operations would provide continuous maritime surveillance, with persistent ISR support 24 hours a day, seven days a week, out to ranges of 2,000 nautical miles from the deployed location (Department of the Navy, 2010). The LCS does not have the Navy Continuous Training Environment (NCTE) synthetic training capability, and Fire Scouts assigned to the LCS will have no capability to train in the NCTE. Integrated training plans for Fire Scout are being developed.

Integrated Training

Triton's MCS will be configured so that it can participate in fleet training exercises synthetically via NCTE. Fleet synthetic training events for BAMS-D and Triton are being developed.

Key Areas of Concern

Airspace Considerations

Airspace planning is a critical requirement when conducting UAS operations but is less of a constraint for UASs in naval operations. The FAA controls the airspace up to the 12-mile limit from land. Navy surface ships with Scan Eagle and Fire Scout can embark the UASs, travel 12 nautical miles out to sea to a naval operating area, then conduct UAS training.

BAMS-D and Triton use special use airspace and fly at altitudes higher than commercial airlines do. They file instrument flight rules flight plans. However, BAMS-D and Triton do not incorporate sense-and-avoid technology, and conflicts can exist with visual flight rules aircraft in the airspace. Airspace issues exist at some Navy training installations as well. For example, along the North Carolina coast, the expeditionary readiness group must work with the FAA to route commercial aircraft around the established restricted operating zone units.

[21] BAMS-D has participated in CSG training events in the Virginia Capes operating area, including combined training unit exercises and joint task force exercises. Navy officials emphasized that Triton is a tactical asset and will respond to the requirements of the task force.

4618 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The Need for Interoperability

So far, this report has emphasized that home-station training is not as effective as it should be, thus reducing the effectiveness of multiservice, or interoperability, training at CTCs and during joint exercises. The importance of interoperability training is stressed in Chairman of the Joint Chiefs of Staff Guide 3501 (2012, pp. B-2 and B-3), which notes that the

> ability of systems, units, or forces to operate in synergy in the execution of assigned tasks is critical to successful operations. This ability to operate effectively together describes interoperability. From a joint training perspective, interoperability is a Service component responsibility. Interoperability training is based on joint doctrine, or where no joint doctrine exists, on Service or [SOF] doctrine to prepare forces or staffs from more than one Service component to respond to operational and tactical requirements deemed necessary by CCDRs [combatant commanders] to execute their assigned missions. Interoperability training involves forces of two or more Service components (including SOF) with no interaction with a CCDR or subordinate JFC [joint force commander] or joint staff.

The publication in 2011 of the MTTP for UASs was designed to address the problem of interoperability. As designed, it is

> a single source, descriptive reference guide to ensure effective planning, integration, and utilization of multi-service UAS capability. It provides commanders, operational staffs, requestors, and UAS operators with a comprehensive resource for planning and employing unmanned aircraft . . . . US Air Force (USAF) uses the term [RPA] for the air vehicle component of a UAS. (MTTP, 2011, p. i)

To date, interoperability training at the NTC and the Joint Readiness Training Center has been limited.[22] GAO (2005, p. 2) cited two significant challenges for improving interoperability training: (1) "establishing effective partnerships with program stakeholders through comprehensive communication and coordination and (2) developing joint training requirements that meet combatant commanders' needs," with particular emphasis on tactical level training (GAO, 2005, p. 2).[23] To meet this challenge, DoD established the Training Transformation Implementation Plan (Director, Readiness and Training Policy and Programs, 2006), giving the Office of the Under Secretary of Defense for Personnel and Readiness overall responsibility and giving the Deputy Under Secretary of Defense for Readiness executive agent responsibility for training transformation planning, programming, budgeting, and execution progress.

---

[22] GAO, 2005, p. 1, found that

> U.S. forces are conducting significantly more complex operations, requiring increased interoperability between and among the military services, combatant commands, and other DOD and non-DOD organizations. In the past, military services experienced some joint operations training during joint exercises, but most service training focused on individual service competencies with limited joint context.

[23] GAO, 2005, p. 18, noted that,

> in the past, joint training tasks were primarily focused at the command level and were identified through DOD authoritative processes that built requirements by translating command combat commanders inputs into training requirements. Training transformation has expanded joint training requirements to include those at the tactical level in addition to joint command level training.

4619 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

While RAND did not assess interoperability training in detail, discussions with the Army's training community, as noted above and as reported in GAO, 2010a, p. 26, suggest that such opportunities have been limited by the lack of Air Force assets, particularly the Predator, due to pressing operational requirements in Iraq and Afghanistan. The problem of transiting Air Force UAVs from Creech AFB to the NTC at Fort Irwin through FAA controlled airspace is often cited. Permanently stationing Air Force UAVs at the NTC would, of course, negate that problem, much as the Marine Corps has done by basing UASs at the MCAGCC at Twentynine Palms, California, to support training there. However, the experience of the Marine Corps suggests that the mere presence of UASs will not ensure that the forces are properly trained. The forces must prepare at their home stations for such training. In addition, given the common MTTP, forces trained to operate with their own services' UASs should find working with UASs from the other services less challenging.

Simulators

Congress has pressed for information on the role that simulators might play in a UAS training strategy, seeking an informed balance between live training and simulated training. In addition, the GAO reported that the

> military services lacked simulators that were capable of supporting training that is intended to build proficiency in skills required of UAS vehicle and sensor operators and prepare these personnel to conduct UAS combat missions. … [And] the Air Force and the Army have not fully developed comprehensive plans that address long-term UAS simulator requirements and associated funding needs. (GAO, 2010a, pp. 27–28)

Implicit in the GAO's comments is an assumption that simulators should play an important role in the future of UAS training. Our review questions that conclusion.

DoD has historically viewed simulator training and joint use of training facilities as an exercise in cost reduction. It is first necessary to understand how simulation better enables the introduction of the technology and, similarly, how joint use of the disruptive technology enables more effective military operations. For the purposes of this report, we have clearly focused on these aspects of simulation and jointness, which must be understood before the more-traditional perspectives of resource allocation can be applied. Currently, the usual significant savings that the department has garnered from simulators in the past do not appear to obtain in this instance. The danger is that, if the department starts with a savings orientation, it will not fully capitalize on the capabilities UASs represent.

For traditional aircraft systems, one major appeal of using simulators, rather than live flying, is the cost differential. For example, a RAND study of the trade-off between live and simulated training for manned aircraft noted that "the Marines and British are starting to give greater recognition to use of simulators as they seek either to reduce the high costs of live training or conserve the limited life of operational aircraft" (Schank et al., 2002, p. 49). In this case, the cost of flying the strike fighter aircraft they were discussing was many times greater than the cost of using a simulator, and the procurement cost of the aircraft itself was also significantly greater than that of the simulator. That said, they also noted that,

4620 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

> [t]o increase that use, several improvements must happen to integrate simulators more fully into their unit training. The fidelity and availability of simulators must increase to the point that fighter pilots see their benefit in training. This requires additional funding for simulators. (Schank et al., 2002, p. 49)

The report further argues that, even given the cost advantage of simulators for strike fighter aircraft training, simulators are a complement to live training, not a substitute for it.

The same point was made to us concerning UAS simulators. Officials of the 432d Wing also noted that simulators were not very good for training on landings. Moreover, a substantial investment in new simulator technology would be necessary to improve the realism of UAS simulators to the point it could prove useful for training UAS crews and ground forces. For example, GAO, 2010a, p. 28, found that currently Air Force and Army simulators did not have the ability

> to replicate all UAS procedures and to enable the integration of UAS training with other types of aircraft, [e.g.,] … the Army's Shadow Institutional Mission Simulator is not currently capable of replicating system upgrades that are being fielded directly to ongoing combat operations, such as a laser target designator and communications relay equipment. … Air Force and Army simulators are also … incapable of providing virtual, integrated training opportunities between manned and unmanned aircraft because of interoperability and information security concerns.

The conditions that make a compelling case for simulators for the training of fighter pilots are largely absent when it comes to UAS training:

- First, UAS flying hours are much less expensive than flying hours for manned aircraft. By one account, the flying hour cost of Shadow was $705; a comparable figure for Gray Eagle was $4,275.[24] By comparison, the Air Force told the GAO that "the live training cost of one F-15E flight hour is approximately $17,449" (Pickup, 2012, pp. 15–16). Other sources peg the flying hour costs of manned aircraft much higher.[25]
- Second, the kinds of operational activities that need more training emphasis, in particular, air-ground coordination, are generally not activities in which simulators *per se* can substitute for live flying. A good example of both the limitations and the value of simulators can be found at the digital air-ground integration ranges the Army operates today. On these ranges, only the weapon system engagement is simulated. Everything else—planning, coordination, UAS operation, ground unit and/or manned aircraft activity, target acquisition—is live.
- Third, while simulators are inherent in the systems used for initial training of pilots and sensor operators,[26] they are not well suited (and not designed) for training operating

[24] Ron Moring, UAS cost per flying hours, personal communication, April 5, 2013. The cost for the Gray Eagle is similar to the costs the Air Force reported for Predator at $3,679 and Reaper at $4,762, as reported by Mark Thompson, "Costly Flight Hours," *Time*, April 2, 2013.

[25] Recently, the Air Force comptroller's office told *Time* that the flying hour cost for the F-15C was $41,921. Other aircraft had considerably higher flying hour costs; e.g., the cost of flying an F-22 for one hour was reported to be $68,362. See Thompson, 2013.

[26] See Shawn Johnson, DAMO-TRC Army Flying Hour Program, "UAS cost per flying hours," personal communication, with Joan Vandervort, Office of the Office USDP&R, April 10, 2013.

4621 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

forces on the full spectrum of UAS capabilities. Simulators may be useful as a supplement to live training of pilots and crews but do not replicate the myriad activities and stimuli that a live training environment provides well for maneuver forces.
- Fourth, as noted previously, simulators at best complement rather than substitute for live training. Given the current state of UAS fielding, first priority must be given to building the live-flying infrastructure. Then, and only then, might funds be used to undertake the research and development that must precede any consideration of fielding the kind of interactive UAS air-ground simulators that could train both UAS crews and ground troops.

In the future, the services should reevaluate the need for virtual training using a cost and effectiveness analysis (COEA) including developmental costs for simulators, the savings based on the costs of flying UASs, and the critical availability of air space for training. Given current budget limitations and the importance of fully developing the opportunities for live training and the relatively low cost of such training, diversion of funds to a research and development program to develop higher-fidelity UAS-ground simulators is not appropriate at this time.

Summary

This chapter presented an overview of UAS training in 2012. Our focus was on service-specific and interoperability training. The training framework presented in Chapter Three was our starting point, with an emphasis on preparing forces for joint training and deployment. We looked at ground, air, and sea forces. Insights came from a wide variety of sources but mainly through visits to selected service bases, where we talked with operators and support personnel, those who train operators and associated team members, and those who train and observe the forces who employ UASs. In general, the RAND team found that qualification training in all the services for designated UAS-specific MOSs is well established. The critical issue is being able to train with ground forces at home station. The experience of the Marine Corps illustrates the importance of such opportunities. The Marine Corps has Shadow squadrons based at the MCAGCC at Twentynine Palms, California, where the restricted airspace is adequate both for maintaining crew proficiency and for supporting ground forces. However, both the ground trainers and squadron personnel the RAND team interviewed reported that the ground forces are not adequately trained at home station to integrate UAS capabilities into their operations. This required starting with what amounted to "remedial" training at Twentynine Palms, and trainees thus did not achieve the level of proficiency desired. This suggests that the biggest challenge in developing and implementing a training strategy for UASs is gaining and maintaining proficiency on the part of end users or "supported units"—the leaders and staffs who will integrate UAS capabilities into their operations.

Thus, as the war in Afghanistan draws to a close, the services must pay close attention not only to training UAS crews and support personnel but also to routinely exercising these systems during combined arms training at home station and at the CTCs. We addressed a number of issues for this, including beddown and support facilities and airspace considerations.

We found that home station training is generally not as effective as it should be, thus reducing the potential effectiveness of multiservice or "interoperability" training at CTCs and during joint exercises. We noted that, to date, interoperability training at the CTCs has been

4622 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

limited by the lack of Air Force assets, particularly the Predator, due to pressing operational requirements in Iraq and Afghanistan. However, given the common MTTP, forces trained to operate with their own service UASs should find working with UASs from the other services less challenging.

Finally, we considered the case for UAS simulators. Currently, such simulators do not appear to offer the significant savings that the Department has usually garnered from simulation in the past. We concluded that, given current budget limitations and the importance of fully developing the opportunities for live training and the relatively low cost of such training, diversion of funds to a research and development program to develop higher fidelity UAS-ground simulators would be unwise at this time.

4623 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

CHAPTER FIVE

Implications and Recommendations

The Guiding Principle: "Train As We Fight"

DoD has been under some pressure from Congress and such organizations as GAO for the lack of central control and the lack of the development of a joint DoD strategy for training. For example, "DOD Lacks a Comprehensive, Results-Oriented Strategy to Resolve UAS Training Challenges," was the summary title of a section of a recent GAO report (GAO, 2010a, p. 29). The Joint Unmanned Aircraft System Center of Excellence was established to support the joint operator and the services by facilitating the development and integration of common unmanned aircraft system operating standards, capabilities, concepts, technologies, doctrine, tactics, techniques, procedures, and training. The center, however, was disestablished in May 2011, and its UAS oversight function was reassigned to the Joint Staff Force Structure, Resources, and Assessment Directorate (J8), with some responsibilities assigned to the UAS Task Force. However, the 2011 publication of the MTTP for UASs addressed the problem of interoperability, and the services have agreed to incorporate the MTTP in their training.
While the services have agreed to a common set of TTP, each service continues to develop its own UASs to meet its own requirements. Moreover, the GAO (2010a, p. 25) has well documented that the opportunity for joint training is limited. While the GAO identified a number of organizations and initiatives addressing UAS training challenges, only one of the eight organizations and initiatives it listed were led by the services. Given the current maturation of UAS platforms, this emphasis is misplaced; the military services employs their UASs in very different ways. Today, the services are still struggling with how to incorporate these new systems. The appropriate strategy for UAS training is to encourage each service to solve its own UAS training problems, then to coordinate the resulting TTPs by updating the MTTP to achieve a high level of interoperability.

Commanders and operators from the bottom up are discovering and adapting to the revolutionary operational changes that UASs have brought about. The most apparent changes are in the persistence and responsiveness of UASs relative to other platforms in the permissive threat environments in which they are currently operating. These characteristics help develop valuable shared situational awareness between UASs and the supported forces and also make ISR capabilities more responsive and immediately available. Processing, exploitation, and dissemination concepts for UAS-generated information, however, are still evolving. In addition, armed UASs provide strike capabilities similar in some ways to those of CAS; the evolution of UASs from pure ISR platforms to small, lightly armed ISR platforms, to bigger, more heavily armed, faster, and even stealthier reconnaissance-strike platforms has crossed operational and cultural seams. This has lead to the need for continual resolution of disputes between intelli-

4624 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

gence and operations staffs over priorities for UASs and their implications for mission planning and execution.

To date, the services have, in a variety of important ways, been "training *while* they fight." Iraq and Afghanistan have served as de facto training ranges, as well as an active theater of war. For example, Air Force Predator and Reaper pilots and sensor operators have frequently gone straight from flight instruction and certification to flying real-world missions, learning and adapting as they support operations. Army and Marine Corps units have also learned in theater how to capitalize on the robust set of capabilities UASs provide.

The demonstrated ability of the services to learn on the fly should be cause for optimism about continued success in UAS training as operations wind down. But that continued success will depend on preserving training opportunities in an environment in which training is not an incidental by-product of operational requirements. Operational experiences, for example, typically do not suffer from the inherent limitations of CONUS training venues, such as limited area, limited time, and limited fidelity. Because of such limitations, it has been harder to train as we fight in CONUS. Infrastructure and other limitations currently make it difficult or impossible to train at night or in bad weather, to train with live or dummy munitions, or to train in a communications environment that represents the environment and demands of actual operations in theater. Preservation of the current levels of proficiency, improvement where needed, and adaptation to changing circumstances will not come without effort; they will require overcoming or at least alleviating the limitations mentioned here.

Elements of a Strategic Training Plan

To *train as we fight*, the DoD training strategy must

- engender better appreciation of UAS capabilities throughout the chain of command
- address organizational, structural, and infrastructure and support issues
- enable training as we fight in collective unit training
- enable training as we fight in larger exercises.

Engender Better Appreciation of UAS Capabilities

Many ground force commanders and their battle staffs today do not fully recognize the potential benefits UASs bring to the fight and, as a result, are not in a position to benefit from them in circumstances that would improve units' warfighting capabilities. This is traceable in part to limited use of UASs in home-station and CTC training but also to other inherent limitations, such as a shortage of experienced personnel and UAS assets and airspace and infrastructure limitations. Overcoming these limitations will enable more opportunities to foster better understanding and improve integration. Training guidance should emphasize the value of UASs, using examples of how units have benefited by preparing themselves to use such systems through training and attending familiarization courses. Such vignettes can be inserted into professional education and training materials to share positive experiences working with UASs.

4625 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Address Organizational, Structural, and Training Infrastructure and Support Issues

Organization and Structure

UASs are a disruptive technology, and their introduction can create tensions between operations and intelligence staffs on the right balance between using UASs to collect intelligence or launch strikes. In the Army, for example, one could ask, is Gray Eagle an ISR asset or an armed reconnaissance system? Doctrine development efforts should produce a doctrine flexible enough to allow changes in allocation and organizational balances and address the attendant training issues accordingly.

Also, in the Army, the organizational placement of UASs remains a challenge, as illustrated by the fact that the assignment of responsibilities for the Raven is still being worked out. A more-systematic approach to monitoring and maintaining Raven operator qualifications will better enable integration of the system into maneuver forces and thus improve overall training and help develop better appreciation of the system's capabilities and limitations. In addition, the Army is currently examining alternatives for placing Shadow platoons in the headquarters company of a brigade combat team or consolidating them in the developing full-spectrum combat aviation brigade. Resolution of these organizational issues will likewise aid in training integration.

Training Infrastructure, Training Support Issues, and Related Factors

Some of the most important ways in which shortfalls can detract from UAS training are

- incompatible or different communications capabilities
- airspace restrictions
- inability to train at night or in bad weather
- inability to use live or dummy munitions
- UAS unavailability
- insufficient time.

These shortfalls cannot always be fully corrected. Some, such as differences in communications capabilities, are inherent but can be alleviated to some extent. The full correction of others may be unaffordable, but partial correction should still be possible. Inability to train at night or in bad weather, for example, is to some extent a result of FAA restrictions on when Air Force UASs can fly from their bases to the NTC. Basing Air Force UASs at the NTC would significantly reduce the effect of these restrictions and might also make it possible for the UASs to use live or dummy munitions, further improving realism for both customers and operators.

Research suggests that airspace restrictions, while sometimes nettlesome, need not pose a serious obstacle to most UAS training at a unit's home station, either for operators or end users. Nevertheless, efforts to gain more access to airspace should continue with the research and development of the joint program for GBSAA systems, led by the Army's program manager for UAS. This system uses ground-based radars to provide an extra layer of airspace safety, which could enable the FAA to make the use of civil airspace adjacent to UAS training airspace less restrictive and thus expand the airspace available for UAS training. A promising initial demonstration with Gray Eagle took place in summer 2011, but GBSAA is not expected to be certified for use until 2015.

The insufficient number of UASs for training should be alleviated to some extent as some systems redeploy from overseas theaters and also by the recent decision to increase the number

4626 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

of Predator/Reaper CAPs from 61 available today to 85 in the future. Similarly, the Operation Enduring Freedom drawdown will likely free up more RPA trainers, alleviating the shortfall.

Enable Training as We Fight in Unit Collective Training

To facilitate home station training, the following steps need to be taken:

- Training must make full use of units' UASs and must use simulation or surrogates, despite their limitations, when live use is not possible.
- Training should include the systems of other services and their associated joint tactical air controllers (JTACs) and air liaison officers (ALOs) to the extent possible.
- Air Force preparation training of JTACs and ALOs should be available for support of unit-level training, as well as for larger exercises.
- After-action reviews and reports should be expanded to reinforce lessons learned; they can also provide a sound basis for continued measurable improvements. Over time, the reports growing out of these documents should become more detailed and should incorporate measures of performance and effectiveness, so that these metrics can drive future improvements.

Enable Training as We Fight in Larger Exercises

By design, larger exercises like those at maneuver CTCs provide considerable opportunities for more-realistic training. They are thus already better postured to provide training on the use and integration of UAS. However, more can be done to enhance the use of training opportunities in such large exercises to further the goal of better UAS integration in the force. Specifically, we recommend

- continued stress on training realism
- including live UASs and their associated JTACs and ALOs as much as possible
- including the CAS-like and ISR missions that UASs, especially Air Force UASs, will be performing in theater
- providing a small paved air strip to base RPAs, launch and recovery elements (LREs), and support crews at the maneuver CTCs to avoid the NAS constraints associated with remote operation
- continued efforts to integrate additional Creech AFB–based UASs into CTC training, when needed.

Initiatives with Likely Near-Term Payoffs

Other things can be done that should provide near-term payoffs:

- **Increase exposure to the capabilities and limitations of UAS—**Continue to expose appropriate commanders to UAS operations through short (one- to two-day) familiarization courses, such as those the Air Force offers at various UAS squadrons' locations (e.g., Creech AFB, Beale AFB, and March ARB). These also need to be introduced as part of the joint training curriculum in a more formal and standardized fashion across the force. The proliferation of Air Force UAS squadrons geographically within CONUS should provide ready access for ground units whatever their home station.

4627 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

- **Harness the lessons-learned process to guide the development of service and joint doctrine and TTP—**Formalize and standardize these processes as appropriate, and share best practices more extensively across services and regions. Right now, most extended learning is done "on the job," with lessons learned shared informally among operators and trainers. Different UAS elements tend to focus support on different ground units, each with geographical and other mission differences. Best practices across these geographic and mission boundaries need to be understood to inform joint doctrine and, hence, responsive training requirements.
- **Address well-known but underresourced training infrastructure shortfalls—**Consider this issue in light of our previous discussions of basing. UASs can be based at maneuver CTCs to minimize the impact of FAA restrictions. If this is done as a part of the drawdown and redeployment of RPA units to CONUS, this should not be too disruptive or expensive; many details remain to be worked out, but military construction and other costs appear to be manageable. Communications infrastructure and C2 organizations and processes at the ranges can be enhanced to better mirror operational capabilities.

Institutionalizing Training for UAS Capabilities over the Longer Term

Institutionalizing UAS training over the longer term will naturally depend on continued support for the specific programs and initiatives and others like them that we outlined earlier. Institutionalization will also require more-general efforts, falling into three broad categories: acculturation, professional development of the UAS force (operators, maintainers, and a UAS chain of command), and integration of the UAS community (a subprofession, if you will) into the aviation profession. These three are somewhat interwoven, and the third depends on the first two. Finally, institutionalization over the longer term will require adaptation: The strategies must be designed to be adaptive, and those who develop and implement them must be willing to adapt them.

Acculturation

The RAND team heard from many sources that many end users do not yet have a well-developed appreciation of the capabilities UASs can bring to an operation. In some cases, this lack of appreciation has derived from negative experiences. Some of these experiences resulted from inexperienced operators, some from mechanical failures, some from sheer bad luck (e.g., weather). The need to deconflict airspace and the need to do so, even when using restricted airspace reserved for military use, often led to utilization problems and contributed to negative impressions about the value of UAS. First impressions do count, and avoiding bad ones is much easier than overcoming them later.

Professional Development

All the services need to maintain professional development strategy for the UAS force. The services are developing a professional force of operators for UASs, both systems and payloads, consisting of enlisted soldiers, noncommissioned officers, and warrant and commissioned officers, although the Army currently has no UAS officer specialty. It is important to develop a cadre of UAS professionals with hands-on experience in all echelons of UAS operation; the Army may

4628 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

wish to consider a career pipeline for such officers, perhaps with an additional skill identifier. Such a professional cadre is a key element in full integration of UAS capabilities.

Integration

The services are making significant efforts to integrate UASs into their force structures. Army efforts would be aided by more access during training to the operational and even strategic capabilities of Air Force UASs. These efforts will be aided by better acculturation and an institutionalized UAS career field that, over time, develops professionals with a more-complete understanding of UAS capabilities and limitations and sufficient rank, technical expertise, and operational experience to enable better integration of the capabilities into the overall operations of the end users. Related issues include integration of UAS capabilities with other ISR systems and with the intelligence warfighting function more generally, the tension between those who value the strike capabilities of UASs and those who value the intelligence collection capabilities, and the further tensions likely to emerge as UAS capabilities widen further. As UAS capabilities grow and broaden, integrating them into other warfighting functions will also present challenges.

Adaptation

The training strategy must adapt to future technical innovations and changes in operational demands. To enable this adaptability, those concerned with overall training strategy development will need to remain cognizant of and to guide the following, where possible:

- evolution of the roles of UASs in the full range of military operations, and the speed and breadth of the expansion of those roles
- surfacing and resolving UAS doctrinal issues (In particular, how will the requirements of intelligence and operations be integrated and deconflicted? How will both organic and nonorganic systems be better integrated to support ground forces, and which warfighting functions will they support? How will technological advances and changes in expected operational conditions influence decisions regarding these roles and missions?)
- service adjustments of force structures and personnel management processes to accommodate the disruptive technology effects of UASs
- influence of the above and related issues on the development, promulgation, and adaptation of joint and service doctrines so these doctrines can continue to form a solid basis for UAS training.

Summary of Findings and Recommendations

Our findings and recommendations are summarized as follows:

1. The proper strategy for DoD at this time is to encourage each service to solve its own UAS training problems, rather than to constrain any one service under the guise of joint operations.
2. DoD should support current and future programs to develop ranges and beddown and support facilities similar to those in the Army's current programs.

4629 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

3. In spite of the demands of deploying units and sustaining combat operations in Afghanistan, Army trainers indicate that Army units are better at maintaining qualification for Shadow qualification than for Raven. Nevertheless, not all units have been able to maintain high Shadow qualification rates—some units arrive at the NTC with one-half or fewer of their operators qualified. Better tracking of operators and their sustainment training is needed, particularly but not exclusively for Ravens.
4. If joint training becomes a priority, the Air Force's current basing and beddown posture will become more of a problem. The Air Force could consider the location of Army hubs when choosing where to base its UAS fleet. A location that is near Army maneuver elements might make airspace access less of a restriction or at least make COAs more practical. Proximity might provide more opportunities for training UAS integration throughout the entire mission planning process.
5. Given current budget limitations and the importance of fully developing the opportunities for live training and the relatively low cost of such training, diversion of funds to a research and development program to develop higher fidelity simulators would seem unwise at this time.

Path to the Future

We have presented and discussed a multitude of means for setting up UAS training strategies for success. These means include support for ongoing facilities and basing initiatives; expansion of such facilities, where possible, to enable wider availability of UASs to support collective training; and efforts to increase the use of UASs—the complete UAS package, including JTACs and other coordinating elements—in collective training, both local and in larger exercises. We have noted the need to support continuing efforts to resolve airspace access issues, observing as we did so that there are ways to keep such restrictions from imposing serious limitations on much of the UAS training envisioned here. Similarly, we have discussed the potential for simulators to add value in training, now and perhaps more in the future. But we have also cautioned that simulators, in their current state, are not a good substitute for live use of UASs in collective training.

The path to the future for UAS strategies starts now, with support for ongoing initiatives that will continue the trends towards better training integration and thus better ability on the part of end users to employ the multiple capabilities of UASs in their operations. The path continues, using that foundation, with longer-term efforts to add to acculturation of end users, professionalization of the UAS community, and integration of the two to harmonize the capabilities of UASs as key elements of overall force effectiveness.

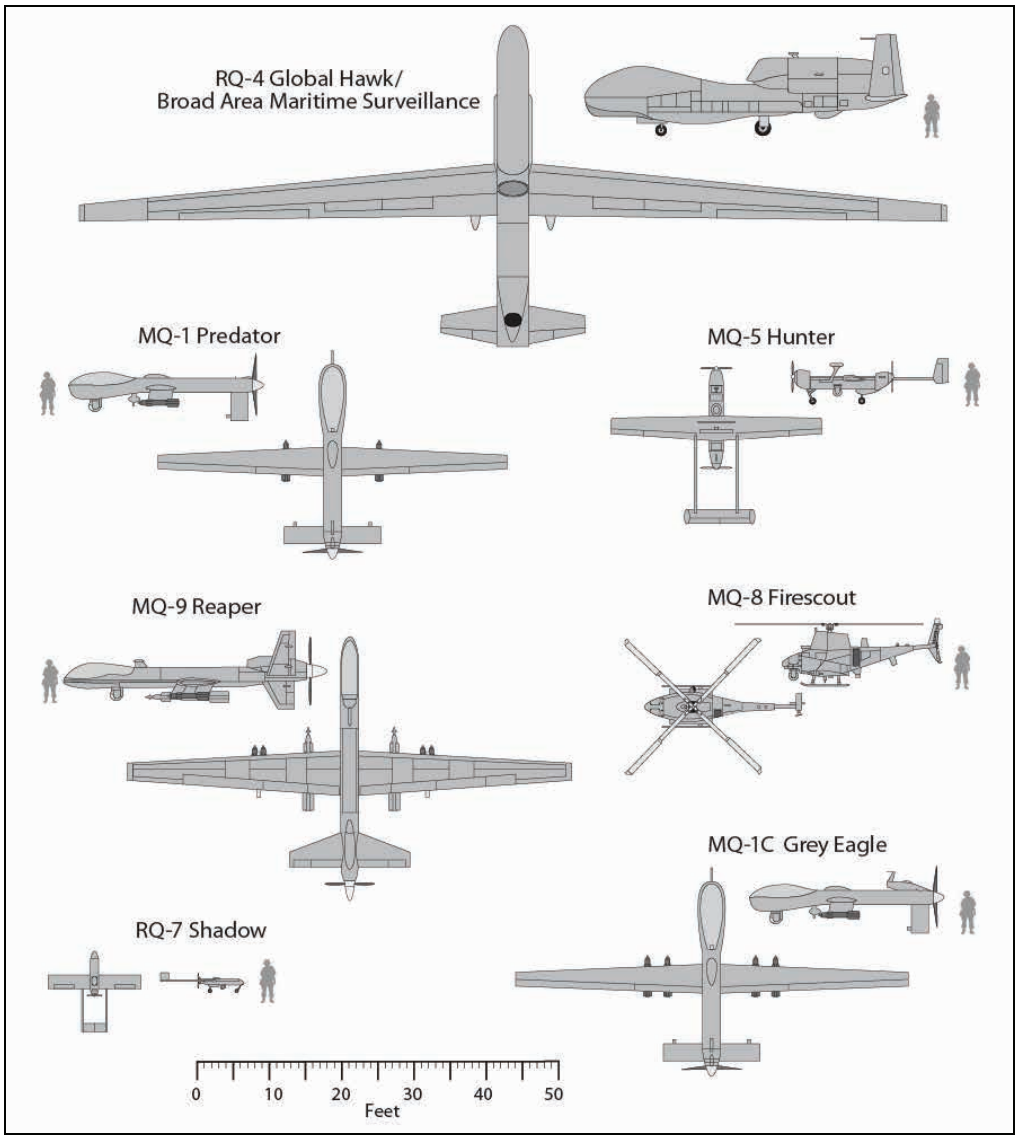
APPENDIX A

Current Major DoD UAS Programs in FY 2012

The following pages come directly from a Congressional Research Service report on U.S. UASs (Gertler, 2012, pp. 31–46).

4632 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Current Major DOD UAS Programs



This section addresses the program status and funding of some of the most prominent UAS programs being pursued by DOD, and most likely to compete for congressional attention. This section does not attempt to provide a comprehensive survey of all UAS programs, nor to develop a classification system for different types of UAS (e.g., operational vs. developmental, single mission vs. multi mission, long range vs. short range). One exception is a short subsection below titled "Small UAVs." The UAVs described in this section are distinguished from the proceeding UAVs by being man-portable and of short range and loiter time. These smaller UAVs are not currently, and are unlikely to be, weaponized. The services do not provide as detailed cost and budget documentation for these UAVs as they do for major UAS programs. Individually, these UAVs appear very popular with ground forces, yet do not necessarily demand as much congressional attention as larger UAS programs like Predator or Global Hawk. As a whole, however, these small, man-portable UAVs appear likely to increasingly compete with major UAS programs for congressional attention and funding.

Table 6. Characteristics of Selected Tactical and Theater-Level Unmanned Aircraft

System	Length (ft)	Wingspan (ft)	Gross weight (lbs)	Payload capacity (lbs)	Endurance (hours)	Maximum altitude (ft)
Predator	27	55	2,250	450	24+	25,000
Grey Eagle	28	56	3,200	800	40	25,000
Reaper	36	66	10,500	3,750	24	50,000

Source: Congressional Budget Office based on data from the Department of Defense's budget request for 2012, Selected Acquisition Reports for December 2010, and Aircraft Procurement Plan: Fiscal Years 2012-2041 (submitted with the 2012 budget, March 2011).

Notes: Acquisition cost includes the cost of procuring air vehicles, sensors, and grounds stations, plus the cost for research. development, test, and evaluation. The services' cost data have been adjusted using CBO's projection of inflation and rounded to the nearest $10 million.

a. The Department of Defense has no plans to acquire or modify the specified system in these years.

b. The cost is for the follow-on aircraft the Air Force plans to acquire instead of the Reaper.

MQ-1 Predator

Through its high-profile use in Iraq and Afghanistan and its multi-mission capabilities, the MQ-1 Predator has become the Department of Defense's most recognizable UAS. Developed by General Atomics Aeronautical Systems in San Diego, CA, the Predator has helped to define the modern role of UAS with its integrated surveillance payload and armament capabilities. Consequently, Predator has enjoyed accelerated development schedules as well as increased

4635 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

procurement funding. The wide employment of the MQ-1 has also facilitated the development of other closely related UAS (described below) designed for a variety of missions.

System Characteristics. Predator is a medium-altitude, long-endurance UAS. At 27 feet long, 7 feet high and with a 48-foot wingspan, it has long, thin wings and a tail like an inverted "V." The Predator typically operates at 10,000 to 15,000 feet to get the best imagery from its video cameras, although it has the ability to reach a maximum altitude of 25,000 feet. Each vehicle can remain on station, over 500 nautical miles away from its base, for 24 hours before returning home. The Air Force's Predator fleet is operated by the 15th and 17th Reconnaissance Squadrons out of Creech Air Force Base, NV; the 11th Reconnaissance Squadron provides training. A second control station has been established at Whiteman AFB, MO.[104] Further, "[t]here are plans to set up Predator operations at bases in Arizona, California, New York, North Dakota, and Texas."[105] The Air Force has about 175 Predators;[106] the CIA reportedly owns and operates several Predators as well.

Mission and Payload. The Predator's primary function is reconnaissance and target acquisition of potential ground targets. To accomplish this mission, the Predator is outfitted with a 450-lb surveillance payload, which includes two electro-optical (E-O) cameras and one infrared (IR) camera for use at night. These cameras are housed in a ball-shaped turret that can be easily seen underneath the vehicle's nose. The Predator is also equipped with a Multi-Spectral Targeting System (MTS) sensor ball which adds a laser designator to the E-O/IR payload that allows the Predator to track moving targets. Additionally, the Predator's payload includes a synthetic aperture radar (SAR), which enables the UAS to "see" through inclement weather. The Predator's satellite communications provide for beyond line-of-sight operations. In 2001, as a secondary function, the Predator was outfitted with the ability to carry two Hellfire missiles. Previously, the Predator identified a target and relayed the coordinates to a manned aircraft, which then engaged the target. The addition of this anti-tank ordnance enables the UAS to launch a precision attack on a time sensitive target with a minimized "sensor-to-shoot" time cycle. Consequently, the Air Force changed the Predator's military designation from RQ-1B (reconnaissance unmanned) to the MQ-1 (multi-mission unmanned).[107] The air vehicle launches and lands like a regular aircraft, but is controlled by a pilot on the ground using a joystick.

MQ-1C Grey Eagle

A slightly larger, longer-endurance version of the Predator, the Army's MQ-1C Grey Eagle entered low-rate initial production on March 29, 2010.[108] The Grey Eagle can remain aloft for 36 hours, 12 hours longer than its Air Force sibling.

An Army platoon operates four aircraft with electro-optical/infrared and/or laser rangefinder/designator payloads, communications relay equipment, and up to four Hellfire

4636 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

missiles. Each platoon includes two ground control stations, two ground data terminals, one satellite communication ground data terminal, one portable ground control station, one portable ground data terminal, an automated takeoff and landing system, two tactical automatic landing systems, and ground support equipment. In total, the program will be 124 aircraft, plus 21 attrition aircraft and 7 schoolhouse aircraft, for a total of 152 aircraft. The average procurement unit cost of a Grey Eagle system is $114.1 million.[109]

MQ-9 Reaper

The MQ-9 Reaper, formerly the "Predator B," is General Atomics' follow-on to the MQ-1. The Reaper is a medium- to high-altitude, long-endurance Predator optimized for surveillance, target acquisition, and armed engagement. While the Reaper borrows from the overall design of the Predator, the Reaper is 13 feet longer and carries a 16-foot-longer wingspan. It also features a 900 hp turboprop engine, which is significantly more powerful than the Predator's 115 hp engine. These upgrades allow the Reaper to reach a maximum altitude of 50,000 feet, a maximum speed of 225 knots, a maximum endurance of 32 hours, and a maximum range of 2,000 nautical miles.[110] However, the feature that most differentiates Reaper from its predecessor is its ordnance capacity. While the Predator is outfitted to carry 2 100-pound Hellfire missiles, the Reaper now can carry as many as 16 Hellfires, equivalent to the Army's Apache helicopter, or a mix of 500-pound weapons and Small Diameter Bombs.

As of February 4, 2011, General Atomics Aeronautical Systems had delivered 65 of 399 planned Reapers, 43 of which are operationally active.[111]

The MQ-9 is operated by the 17th Reconnaissance Squadron and the 42nd Attack Squadron, both at Creech Air Force Base, NV, and the 29th Attack Squadron at Holloman AFB, NM.[112]

Program Status. Predator–family UAS are operated as part of a system, which consists of four air vehicles, a ground control station, and a primary satellite link. The unit cost in FY2009 for one Predator system was approximately $20 million,[113] while the average procurement unit cost for a Reaper system was $26.8 million.[114]

RQ-4 Global Hawk

Northrop Grumman's RQ-4 Global Hawk has gained distinction as the largest and most expensive UAS currently in operation for the Department of Defense. Global Hawk incorporates a diverse surveillance payload with performance capabilities that rival or exceed most manned spy planes. However, Pentagon officials and Members of Congress have become increasingly concerned with the program's burgeoning cost, which resulted in Nunn-McCurdy breaches in April 2005 and April 2011.[115] Also, the RQ-4B Block 30 was deemed "not operationally suitable" due to "low air vehicle reliability" by the office of Operational Test and Evaluation in May 2011.[116]

System Characteristics. At 44 feet long and weighing 26,750 lbs, Global Hawk is about as large as a medium sized corporate jet. Global Hawk flies at nearly twice the altitude of commercial airliners and can stay aloft at 65,000 feet for as long as 35 hours. It can fly to a target area 5,400 nautical miles away, loiter at 60,000 feet while monitoring an area the size of the state of Illinois for 24 hours, and then return. Global Hawk was originally designed to be an autonomous drone capable of taking off, flying, and landing on pre-programmed inputs to the UAV's flight computer. Air Force operators have found, however, that the UAS requires frequent intervention by remote operators.[117] The RQ-4B resembles the RQ-4A, yet features a significantly larger airframe. In designing the B-model, Northrop Grumman increased the Global Hawk's length from 44 feet to 48 feet and its wingspan from 116 feet to 132 feet. The expanded size enables the RQ-4B to carry an extra 1000 pounds of surveillance payload.

[115] Amy Butler, "USAF Declares Second Major Global Hawk Cost Breach," Aerospace Daily, April 13, 2011. The 2005 breach stemmed from costs in transitioning from the Block 10 Global Hawk to the larger Block 30; the 2011 breach was attributed primarily to reduced procurement quantities rather than issues with the program.

4638 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Mission and Payload. The Global Hawk UAS has been called "the theater commander's around-the-clock, low-hanging (surveillance) satellite."[118] The UAS provides a long-dwell presence over the battlespace, giving military commanders a persistent source of high-quality imagery that has proven valuable in surveillance and interdiction operations. The RQ-4A's current imagery payload consists of a 2,000-lb integrated suite of sensors much larger than those found on the Predator. These sensors include an all-weather SAR with Moving Target Indicator (MTI) capability, an E-O digital camera and an IR sensor. As the result of a January 2002 Air Force requirements summit, Northrop Grumman expanded its payload to make it a multi-intelligence air vehicle. The subsequent incarnation, the RQ-4B, is outfitted with an open-system architecture that enables the vehicle to carry multiple payloads, such as signals intelligence (SIGINT) and electronic intelligence (ELINT) sensors. Furthermore, the classified Multi-Platform Radar Technology Insertion Program (MP-RTIP) payload will be added in order to increase radar capabilities. These new sensor packages will enable operators to eavesdrop on radio transmissions or to identify enemy radar from extremely high altitudes. Future plans include adding hyper-spectral sensors for increased imagery precision and incorporating laser communications to expand information transfer capabilities.[119] The end goal is to field a UAS that will work with space-based sensors to create a "staring net" that will prevent enemies from establishing a tactical surprise.[120] In August 2003, the Federal Aviation Administration granted the Global Hawk authorization to fly in U.S. civilian airspace, which further expanded the system's mission potential.[121] This distinction, in combination with the diverse surveillance capabilities, has led many officials outside the Pentagon to consider the Global Hawk an attractive candidate for anti-drug smuggling and Coast Guard operations.[122]

Program Status. Developed by Northrop Grumman Corporation of Palmdale, CA, Global Hawk entered low-rate initial production in February 2002. The Air Force has stated that it intends to acquire 51 Global Hawks, at an expected cost of $6.6 billion for development and procurement costs. As of November 2009, the Air Force possessed 7 RQ-4As and 3 RQ-4Bs.[123] Another 32 Global Hawks had been authorized and appropriated through FY2011.[124] According to the most recent Selected Acquisition Report, the current average procurement unit cost for the Global Hawk has reached $140.9 million in current dollars.[125]

In April 2005, the Air Force reported to Congress that the program had overrun by 18% as a result of an "increasing aircraft capacity to accommodate requirements for a more sophisticated, integrated imagery and signals intelligence senor suite."[126] A Government Accountability Office report in December 2004 noted that the program had increased by nearly $900 million since 2001 and recommended delaying the purchase of future Global Hawks until an appropriate

4639 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

development strategy could be implemented.[127] The rising costs of the UAV and accusations of Air Force mismanagement have caused concern among many in Congress and in the Pentagon as well as facilitating an overall debate on the Air Force's development strategy.[128]

Following a 2010 Defense Acquisition Board review of the Global Hawk program,

> Air Force acquisition executive David Van Buren told reporters that he is "not happy" with the pace of the program, both on the government and the contractor side. Chief Pentagon arms buyer Ashton Carter also criticized the program, saying that it was "on a path to being unaffordable."[129]

In April 2011, a reduction in the number of Global Hawk Block 40 aircraft requested in the FY2012 budget from 22 to 11 caused overall Global Hawk unit prices to increase by 11%, again triggering Nunn-McCurdy.[130]

In its markup of the FY2011 defense authorization bill, the House Armed Services Committee expressed concern "that differing, evolving service unique requirements, coupled with Global Hawk UAS vanishing vendor issues, are resulting in a divergence in each service's basic goal of maximum system commonality and interoperability, particularly with regard to the communications systems." The bill report directs the Under Secretary of Defense for Acquisition, Technology, and Logistics to certify and provide written notification to the congressional defense committees by March 31, 2011, that he has reviewed the communications requirements and acquisition strategies for both Global Hawk and BAMS. The subcommittee wants assurance that the requirements for each service's communications systems have been validated and that the acquisition strategy for each system "achieves the greatest possible commonality and represents the most cost effective option" for each program.[131]

A May 20, 2011, report from the Air Force Operational Test and Evaluation Center found the Global Hawk Block 20/30 to be "effective with significant limitations ... not suitable and partially mission capable." The report cited "lackluster performance of the EISS imagery collector and ASIP sigint collectors at range" rather than issues with the Global Hawk airframe itself.[132]

a. As passed, H.R. 6523, the Ike Skelton National Defense Authorization Act For Fiscal Year 2011, did not include program-level detail, so no amounts were specified for these program elements.

BAMS

The Navy's Broad Area Maritime Surveillance system is based on the Global Hawk Block 20 airframe but with significantly different sensors from its Air Force kin. This, coupled with a smaller fleet size, results in a higher unit cost. "The air service's drone costs $27.6 million per copy, compared to an expected $55 million per BAMS UAV, including its sensors and communications suite…. At 68 aircraft, the BAMS fleet will be the world's largest purchase of long-endurance marinized UAVs."[133]

System Characteristics and Mission. "BAMS ... provides persistent maritime intelligence, surveillance, and reconnaissance data collection and dissemination capability to the Maritime Patrol and Reconnaissance Force. The MQ-4C BAMS UAS is a multi-mission system to support strike, signals intelligence, and communications relay as an adjunct to the MMA/P-3 community to enhance manpower, training and maintenance efficiencies worldwide."[134]

"The RQ-4 ... features sensors designed to provide near worldwide coverage through a network of five orbits inside and outside continental United States, with sufficient air vehicles to remain airborne for 24 hours a day, 7 days a week, out to ranges of 2000 nautical miles. Onboard sensors will provide detection, classification, tracking and identification of maritime targets and include maritime radar, electro-optical/infra-red and Electronic Support Measures systems. Additionally, the RQ-4 will have a communications relay capability designed to link dispersed forces in the theater of operations and serve as a node in the Navy's FORCEnet strategy."[135]

[135] Department of Defense, *Department of Defense Fiscal Year 2012 Budget Estimates, Research, Development, Test & Evaluation, Navy*, Budget Activity 7, February 2011.

4641 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

"The drones ... will collect information on enemies, do battle-damage assessments, conduct port surveillance and provide support to Navy forces at sea. Each aircraft is expected to serve for 20 years."[136]

Program Status. The Administration's FY2012 budget request documents place Milestone C for BAMS in the third quarter of FY2013, with initial operational capability in the first quarter of 2016. "Since Milestone B for the Navy BAMS UAS program, identifying opportunities for the RQ-4-based BAMS and Global-Hawk programs has been a significant interest item for the UAS TF and has been well documented within the Department."[137] In one effort to integrate development, on June 12, 2010, the Navy and Air Force concluded a Memorandum of Agreement (MOA) regarding their Global Hawk and BAMS programs, which use a common airframe. "Shared basing, maintenance, command and control, training, logistics and data exploitation are areas that could be ripe for efficiencies, says Lt. Gen David Deptula, Air Force deputy chief of staff for intelligence, surveillance and reconnaissance…. Also, a single pilot and maintenance training program is being established at Beale AFB, Calif., for both fleets."[138] However, issues still exist over common control stations and whether one service's pilots should be able to operate the other service's aircraft.

MQ-8B Fire Scout

Now in deployment, the Fire Scout was initially designed as the Navy's choice for an unmanned helicopter capable of reconnaissance, situational awareness, and precise targeting.[139] Although the Navy canceled production of the Fire Scout in 2001, Northrop Grumman's vertical take-off UAV was rejuvenated by the Army in 2003, when the Army designated the Fire Scout as the interim Class IV UAV for the future combat system. The Army's interest spurred renewed Navy funding for the MQ-8, making the Fire Scout DOD's first joint UAS helicopter.

System Characteristics and Mission. Northrop Grumman based the design of the Fire Scout on a commercial helicopter. The RQ-8B model added a four-blade rotor to reduce the aircraft's acoustic signature.[140] With a basic 127-pound payload, the Fire Scout can stay aloft for up to 9.5 hours; with the full-capacity sensor payload, endurance diminishes to roughly 6 hours. Fire Scout possesses autonomous flight capabilities. The surveillance payload consists of a laser designator and range finder, an IR camera and a multi-color EO camera, which when adjusted with specific filters could provide mine-detection capabilities.[141] Fire Scout also currently possesses line-of-sight communication data links. Initial tests of an armed Fire Scout were conducted in 2005, and the Navy expects to add "either Raytheon's Griffin or BAE's Advanced Precision Kill Weapon System" small missiles to currently deployed Fire Scouts soon.[142] Discussions of future missions

[142] Joshua Stewart, "Navy plans to arm Fire Scout UAV with missiles," *Navy Times*, August 18, 2011.

4642 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

have also covered border patrol, search and rescue operations, medical resupply, and submarine spotting operations.

Program Status. Six production MQ-8 air vehicles have been delivered to date.[143] The Pentagon's 2009 UAS Roadmap estimates a future inventory of 131 RQ-8Bs for the Navy to support the Littoral Combat Ship class of surface vessels.[144] The Army had intended to use the Fire Scout as the interim brigade-level UAV for its Future Combat System program,[145] but canceled its participation in January, 2010.[146]

A Fire Scout attracted media attention in August 2010, when it flew through Washington, DC, airspace after losing its control link. "A half-hour later, Navy spokesmen said, operators re-established control and the drone landed safely."[147]

FIRE-X/MQ-8C

The FIRE-X project, recently designated MQ-8C but continuing the Fire Scout name, is a developmental effort to adapt the Fire Scout software and navigation systems to a full-size standard helicopter. The Navy "is to award Northrop Grumman a contract to supply 28 MQ-8C Fire Scout ... to be fielded by the first quarter of 2014 to meet an urgent operational requirement."[148]

> Fire Scout can fly for 8 hours with a maximum range of 618 nautical miles? Well, Fire-X will fly for 15, with a max range of 1227. Fire Scout tops out at 100 knots? Fire-X can speed by at 140. Fire-X will carry a load of 3200 lbs. to Fire Scout's 1242. All this talk from a drone helicopter that just took its first flight in December.... Fire-X isn't going to be a big departure from Fire Scout, though. The BRITE STAR II and other radars will remain on board, as will its software for relaying information to a ship.[149]

RQ-170 Sentinel

Although publicly acknowledged to exist, most information about the Lockheed Martin RQ-170 Sentinel is classified. First photographed in the skies over Afghanistan, but also reportedly in operation from South Korea,[150] the RQ-170 is a tailless "flying wing" stealthier than other current

4643 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

U.S. UAS. An RQ-170 was reported to have performed surveillance and data relay related to the operation against Osama bin Laden's compound on May 1, 2011. The government of Iran claimed on December 2, 2011, to be in possession of an intact RQ-170 following its incursion into Iranian airspace.

System Characteristics. Built by Lockheed Martin, the RQ-170 has a wingspan of about 65 feet and is powered by a single jet engine. It appears to have two sensor bays (or satellite dish enclosures) on the upper wing surface. Although an inherently low-observable blended wing/fuselage design like the B-2, the RQ-170's conventional inlet, exhaust, and landing gear doors suggest a design not fully optimized for stealth.[151]

Potential Mission and Payload. "The RQ-170 will directly support combatant commander needs for intelligence, surveillance and reconnaissance to locate targets."[152]

Program Status. "The RQ-170 is a low observable unmanned aircraft system (UAS) being developed, tested and fielded by the Air Force."[153] No further official status is available.

Other Current UAS Programs

RQ-5A Hunter/MQ-5B Hunter II

Originally co-developed by Israel Aircraft Industries and TRW (now owned by Northrop Grumman) for a joint U.S. Army/Navy/Marine Corps short-range UAS, the Hunter system found a home as one of the Army's principal unmanned platforms. The service has deployed the RQ-5A for tactical ISR in support of numerous ground operations around the world. At one time, the Army planned to acquire 52 Hunter integrated systems of eight air vehicles apiece, but the Hunter program experienced some turbulence. The Army canceled full-rate production of the RQ-5A in 1996, but continued to use the seven systems already produced. It acquired 18 MQ-5B Hunter IIs through low-rate initial production in FY2004 and FY2005. The MQ-5B's design includes longer endurance and the capability to be outfitted with anti-tank munitions. Both variants are currently operated by the 224th Military Intelligence Battalion out of Fort Stewart, GA; by the 15th Military Intelligence Battalion out of Ft. Hood, TX; and by 1st Military Intelligence Battalion out of Hohenfels, Germany.

System Characteristics. The RQ-5A can fly at altitudes up to 15,000 feet, reach speeds of 106 knots, and spend up to 12 hours in the air. Weighing 1,600 pounds, it has an operating radius of 144 nautical miles. The MQ-5B includes an elongated wingspan of 34.3 feet up from 29.2 feet of the RQ-5A and a more powerful engine, which allows the Hunter II to stay airborne for three extra hours and to reach altitudes of 18,000 feet.[154] The Hunter system consists of eight aircraft, ground control systems and support devices, and launch/recovery equipment. In FY2004, the final year of Hunter procurement, a Hunter system cost $26.5 million.

4644 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Mission and Payload. The Army has mostly used the Hunter system for short- and medium-range surveillance and reconnaissance. More recently, however, the Army expanded the Hunter's missions, including weaponization for tactical reconnaissance/strike operations with the GBU-44/B Viper Strike precision guided munition, which can designate targets either from the munition's laser, from another aerial platform, or from a ground system. This weapon makes the Hunter the Army's first armed UAS. "Also, in 2004, the Department of Homeland Security, Customs and Border Protection Bureau, and Office of Air and Marine utilized Hunter under a trial program for border patrol duties. During this program, the Hunter flew 329 flight hours, resulting in 556 detections."[155]

Program Status. The Army halted Hunter production in 2005. As of May 2011, 45 Hunter UAVs were still in operation and periodically receiving upgrades and modifications. In August 2005, the Army awarded General Atomics' Warrior UAS (which later became Grey Eagle) the contract for the Extended Range-Multi Purpose UAS program over the Hunter II.[156]

RQ-7 Shadow

The RQ-7 Shadow found a home when the Army, after a two-decade search for a suitable system, selected AAI's close range surveillance platform for its tactical unmanned aerial vehicle (TUAV) program. Originally, the Army, in conjunction with the Navy explored several different UAVs for the TUAV program, including the now-cancelled RQ-6 Outrider system. However, in 1997, after the Navy pursued other alternatives, the Army opted for the low-cost, simple design of the RQ-7 Shadow 200. Having reached full production capacity and an IOC in 2002, the Shadow has become the primary airborne ISR tool of numerous Army units around the world and is expected to remain in service through the decade.

The Administration's FY2011 budget request did not include funding for Shadow aircraft, although it did include continued RDT&E funding for Shadow.[157]

System Characteristics. Built by AAI Corporation (now owned by Textron), the Shadow is 11 feet long with a wingspan of 13 feet. It has a range of 68 nautical miles, a distance picked to match typical Army brigade operations, and average flight duration of five hours. Although the Shadow can reach a maximum altitude of 14,000 feet, its optimum level is 8,000 feet. The Shadow is catapulted from a rail-launcher, and recovered with the aid of arresting gear. The UAS also possesses automatic takeoff and landing capabilities. The upgraded version, the RQ-7B Shadow, features a 16-inch greater wingspan and larger fuel capacity, allowing for an extra two hours of flight endurance.

Mission and Payload. The Shadow provides real-time reconnaissance, surveillance, and target acquisition information to the Army at the brigade level. A potential mission for the Shadow is the perilous job of medical resupply. The Army is considering expanding the UAS's traditional missions to include a medical role, where several crucial items such as blood, vaccines, and fluid

infusion systems could be delivered to troops via parachute.[158] For surveillance purposes, the Shadow's 60-pound payload consists of an E-O/IR sensor turret, which produces day or night video and can relay data to a ground station in real-time via a line-of-sight data link. As part of the Army's Future Combat System plans, the Shadow will be outfitted with the Tactical Common Data Link currently in development to network the UAS with battalion commanders, ground units, and other air vehicles.[159] The Marine Corps is considering how to arm Shadow.[160]

Program Status. The Army and Marine Corps currently maintain an inventory of 364 Shadow UAVs.[161] The program cost for a Shadow UAV system—which includes four vehicles, ground control equipment, launch and recovery devices, remote video terminals, and High Mobility Multipurpose Wheeled Vehicles for transportation—reached $11.1 million in current year dollars for FY2008.[162] The Army procured 102 systems through 2009.[163] In FY2012, the Army requested $25 million for 20 Shadow aircraft to replace combat losses, and approximately $200 million for payload upgrades.

"Small UAVs"

RQ-14 Dragon Eye

AeroVironment's Dragon Eye is a backpack-carried, battery-operated UAV employed by the Marines at the company level and below for reconnaissance, surveillance, and target acquisition. Dragon Eye features a 3.8-foot rectangular wing, twin propellers, and two camera ports each capable of supporting day-light electro-optical cameras, low-light TV cameras, and infrared cameras. The compact and lightweight design of the UAV allows an operational endurance of 45 minutes and can travel as far as 2.5 nautical miles from the operator. Low-rate-initial-production of 40 aircraft began in 2001. After a 2003 operational assessment, the Marine Corps awarded AeroVironment a contract to deliver approximately 300 systems of full-rate-production Dragon Eyes.[164] However, that contract was later revised to acquire Raven UAS instead. One Dragon Eye system consists of three air vehicles and one ground station. The final Marine Corps procurement budget request in FY2006 anticipated the current unit cost per Dragon Eye system as $154,000.[165]

FQM-151 Pointer

Although procurement of this early UAS began in 1990, the electric-powered Pointer has seen service in Operation Enduring Freedom (OEF) and Operation Iraqi Freedom (OIF). Pointer is a

short-range reconnaissance and battlefield surveillance UAV developed by AeroVironment. Its flight endurance (two hours) is greater than most similar small UAVs, in part due to its relatively large, 9-foot wingspan. That wingspan decreases portability of the 8.5-pound Pointer, and as a result, transportation of a Pointer system (two air vehicles and a ground control unit) requires two personnel. Although superseded by the Raven (below), Pointer remains a valued short-range ISR asset for the Air Force and Special Operations Command.

RQ-11 Raven

Engineered from the basic design of the Pointer, the Raven is two-thirds the size and weight of its predecessor, with a much smaller control station, making the system man-portable.[166] "The RQ-11A is essentially a down-sized FQM-151 *Pointer*, but thanks to improved technology can carry the same navigation system, control equipment, and payload."[167] The Raven provides Army and SOCOM personnel with "over-the-hill" reconnaissance, sniper spotting, and surveillance scouting of intended convoy routes. The electric motor initiates flight once hand-launched by a running start from the ground operator. The vehicle is powered by an electric battery that needs to be recharged after 90 minutes, but deployed soldiers are equipped with four auxiliary batteries that can be easily charged using the 28 volt DC outlet in a Humvee. The vehicle lands via a controlled crash in which the camera separates from the body, which is composed of Kevlar plating for extra protection. Like the Pointer, the Raven can carry either an IR or an E-O camera and transmits real-time images to its ground operators. The relatively simple system allows soldiers to be trained in-theater in a matter of days. Raven systems can either be deployed in three-aircraft or two-aircraft configurations. "Raven was adopted as the US Army's standardised short range UAV system in 2004 with a total of 2469 air vehicles (including older RQ-11A series models) in operational service by mid 2007."[168] "The US Army has an ongoing acquisition objective for about 2,200 Raven systems and has taken delivery of more than 1,300 to date."[169] A three-aircraft system costs approximately $167,000.[170]

ScanEagle

Developed by the Insitu Group (owned by Boeing) as a "launch-and-forget" UAV, the ScanEagle autonomously flies to points of interest selected by a ground operator.[171] The ScanEagle has gained notice for its long endurance capabilities and relative low cost. The gasoline-powered UAV features narrow 10 foot wings that allow the 40-pound vehicle to reach altitudes as high as 19,000 feet, distances of more than 60 nautical miles, and a flight endurance of almost 20 hours. Using an inertially stabilized camera turret carrying both electro-optical and infrared sensors, ScanEagle currently provides Marine Corps units in Iraq with force-protection ISR and is also used by Special Operations Command. ScanEagle operations began in 2004,[172] and continue

today. Although ScanEagle was expected to cost about $100,000 per copy, the Navy and SOCOM have contracted for operations instead of procurement, with Boeing providing ISR services utilizing ScanEagle under a fee-for-service arrangement.[173]

ScanEagle is also in use by non-military organizations for surveillance purposes, including tracking whale migrations.[174]

Small Tactical Unmanned Aerial System (STUAS)

In July 2010, the Department of the Navy awarded Insitu a two-year, $43.7 million contract for the design, development, integration, and test of the Small Tactical Unmanned Aircraft System (STUAS) for use by the Navy and Marine Corps to provide persistent maritime and land-based tactical reconnaissance, surveillance, and target acquisition (RSTA) data collection and dissemination. "For the USMC, STUAS will provide the Marine Expeditionary Force and subordinate commands (divisions and regiments) a dedicated ISR system capable of delivering intelligence products directly to the tactical commander in real time. For the Navy, STUAS will provide persistent RSTA support for tactical maneuver decisions and unit-level force defense/force protection for Navy ships, Marine Corps land forces, and Navy Special Warfare Units."[175]

Payloads include day/night video cameras, an infrared marker, and a laser range finder, among others. STUAS can be launched and recovered from an unimproved expeditionary/urban environment, as well as from the deck of Navy ships.[176]

STUAS uses Insitu's Integrator airframe, which uses common launch, control, and recovery equipment with ScanEagle. STUAS has a takeoff weight of up to 125 pounds with a range of 50 nautical miles. However, STUAS will be procured and operated by the services rather than operated on a fee-for-service basis because "the Scan Eagle's current fee-for-service contract limits the way the UAS is deployed ... with Boeing/Insitu employees usually operating the aircraft in the field due to liability issues." Procuring the system will allow the services to train their own operators. Initial operating capability is expected in the fourth quarter of FY2013.[177]

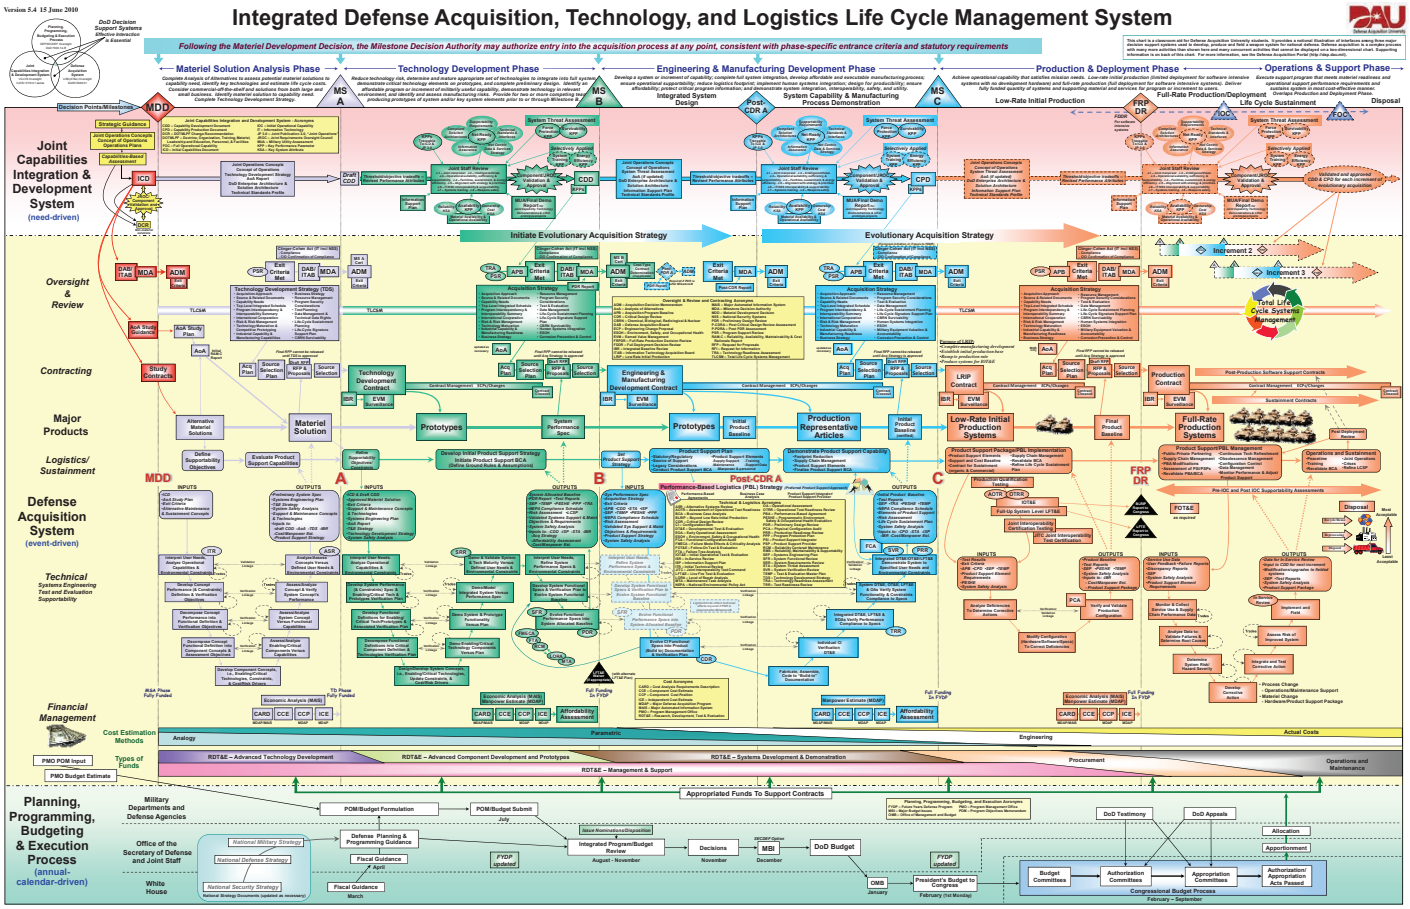
APPENDIX B

The Department of Defense's Traditional Acquisition System

Overview

The DAS is a structured and deliberate process for establishing requirements and planning and resourcing the procurement of new capabilities. The need for accountability and oversight in the allocation of national resources has led to the buildup over decades of a large bureaucratic apparatus around the DAS. The complexity of the process can be seen in Figure B.1.

This bureaucracy has many virtues. It provides for a structured process governed by regulations and accountable authorities and includes provisions for relatively stable funding over system life cycles. Such provisions are far from perfect. For example, observers have long noted that the process can be slow and unresponsive to the immediate needs of warfighters. Such concerns have led, as will be discussed below, to evolving roles for the combatant commanders in resource allocation processes. Another concern is that provision of training and sustainment considerations, while formally required, is an afterthought to the acquisition and fielding of new equipment. Both concerns will be discussed below.



Role of Combatant Commanders in Traditional Acquisition

To meet current warfighter needs, the DoD has in recent years advanced changes to some existing acquisition processes and relationships. As a result, the roles of the COCOMs in the traditional system have evolved. For example, the Secretary of Defense approved a "streamlined and refocused" integrated priority list process to better support the development of service program objective memorandums (Hicks et al., 2008, p. 59). In November 2005, the Vice Chairman of the Joint Chiefs of Staff launched a process by which the Joint Requirements Oversight Council, in consultation with the COCOMs, identified a list of "most pressing" military issues to support resourcing and planning decisions (Hicks et al., 2008, p. 59). In 2006 the Senior Warfighters Forum, consisting of COCOM deputies, began meeting every four to six weeks to discuss coordination issues, and the Vice Chairman of the Joint Chiefs of Staff began coordinating regular trips to the COCOMs with critical PPBE decision points to better represent the COCOM position in resourcing decisions (Hicks et al., 2008, p. 60). Furthermore, SOCOM's traditional acquisition activities have increased, and its budget has grown significantly (GAO, 2007b, p. 1).

The COCOMS do not lead the process, but their ability to participate in acquisition, particularly in identifying requirements, has expanded. An emphasis on warfighting in recent years has given new weight to the capabilities and solutions that the COCOMs identify as

RAND *RR440-B.1*

4651 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

required. Beyond the current fight, however, observers argue that the nature of future challenges and the technology necessary to meet them are so dynamic that fundamental acquisition relationships need to be rethought. As the commander of SOUTHCOM recently wrote:

> We are living in an age of rapid change facilitated by advancing technologies and increasingly networked systems, societies, and economies. In order for security agencies to be successful in this complex environment, those organizations must be flexible, open and forward-thinking. (Stavridis, 2010, p. xxii)

Leadership of traditional acquisition processes is vested in the military departments (the force providers) rather than the combatant commanders (the force users). The DAS consists of the interrelationship between the establishment of requirements (Joint Capabilities Integration and Development), the process of providing solutions, and the allocation of resources (PPBE). All processes are primarily driven by the military departments, with some inputs from the COCOMs. The logic behind the vesting of acquisition authority in the military departments reflects both Title 10 responsibilities and unique competencies for acquisition. The division of labor has traditionally been that the COCOMs provide inputs to the determination of requirements, and the services lead on providing solutions. A recent RAND assessment concluded that it "is the job of those in Washington, D.C., to reach out to the COCOMs and demonstrate that their needs are being addressed, rather than turn the process over to them" (Blickstein and Nemfakos, 2009, p. 7). Traditionally, the COCOMs are viewed as best suited to fighting wars, while the military departments are best suited to balancing other priorities and managing resource decisionmaking.

APPENDIX C

Military Value Analysis of Unmanned Aircraft System Training Bases

Training Locations

The information on specific training locations included in this appendix is drawn from RAND interviews, service presentations to congressional oversight committees, and Army surveys and consolidated snapshots of selected Army bases compiled in November 2012.

Initial training for UAS operators and sensor operators is concentrated at a few locations. The Air Force uses Beale AFB for training its Global Hawk crews and primarily Holloman AFB for its Predator crews.[1] The Navy plans to leverage the similarities between the Global Hawk and BAMS by having some joint training at Beale AFB. The Army conducts all its initial UAS training at Fort Huachuca, Arizona. The Marine Corps trains its Shadow crews with the Army.[2] Current and continuing pressures on the defense budget are likely to result in further changes. We limited our efforts to analyze military value in depth to activities that any training base would more certainly include, regardless of budget reductions. After we gain a fuller understanding of the results of Secretary of Defense decisions on the content of the FY 2014 and FY 2015 programs, we will renew our efforts to complete this military value analysis.

The approach to the *military value analysis of training bases* presented here is based on the Department of the Navy's 1995 Base Realignment and Closure documents. These categories and a brief description are listed below:

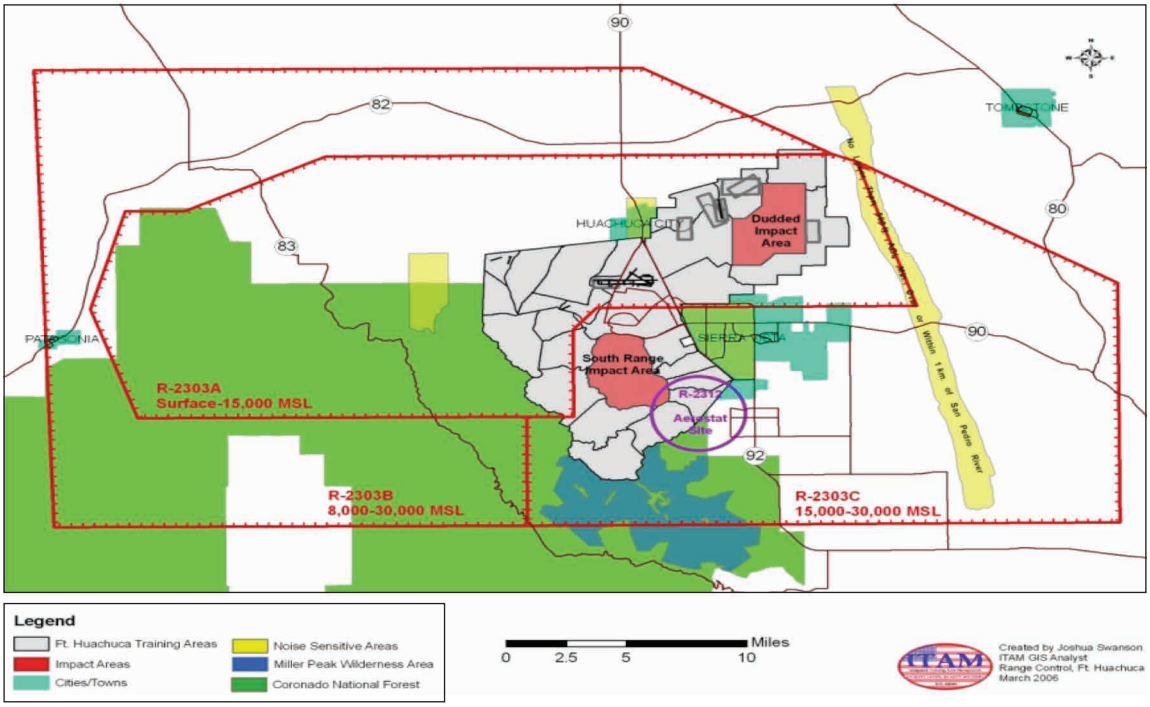
- flight training areas and airspace—covers access to special use airspace, availability of training areas, etc.
- airfield and maintenance facilities—includes facilities available for housing and maintaining the aircraft
- expansion potential—any comments on future plans for expansion or capacity for expansion
- training and training facilities—includes classrooms or other similar infrastructure and equipment required for training
- military and general support mission—any impacts of the other military missions housed at the same installation

[1] The training for the LRE is separate from the FTU and takes place at Creech AFB, Nevada.

[2] The Marines will also operate the RQ-20A Puma. We do not discuss the training for that SUAS.

4654 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

- weather—any impacts of weather on training capacity
- location—description of the where the installation is located
- base loading—comments on consolidation of training.



Army RQ-7 and MQ-1C Training IQT Fort Huachuca, Arizona

Fort Huachuca, Arizona, is home to the 2-13th Aviation Regiment (formally the Unmanned Aircraft Systems Training Battalion). The 2-13th trains operators and maintainers for the RQ-7 Shadow, the Warrior Alpha, and the MQ-1C Gray Eagle. The training pipeline for each of these was described in the body of this report.

Flight Training Areas and Airspace

See Figure C.1. R-2303 is a major operational area used for airspace manned and unmanned operations, Army and joint service training along with Department of Homeland Security border security operations. Fort Huachuca is the controlling authority and so can activate this restricted use airspace on demand, at any time. It covers 850 mi^2 of land outside Fort Huachuca and encompasses 4,600 mi^3 of airspace from the surface to 30,000 feet, much of it over private land. The FAA has issued several waivers to ensure the safe operations of manned and unmanned traffic. The area also has unencumbered radio frequency spectrum for the foreseeable future.

Figure C.1
Airspace Surrounding Fort Huachuca

RAND *RR440-C.1*

4655 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Airfield and Maintenance Facilities

See Figure C.2. UAS operations split between the Libby Army Airfield and Black Tower. Shadow and Hunter training takes place at Black Tower. There are dedicated maintenance facilities as well as hangers and airstrips. Gray Eagle training takes place at Libby Army Airfield.

Expansion Potential

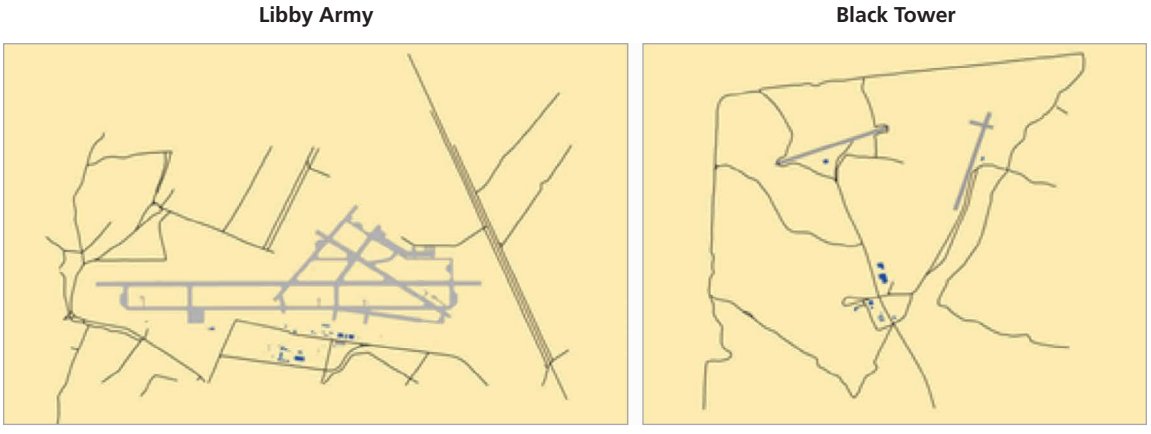
The IQT common core and the course for Shadow are currently running 24-hour operations. It would be difficult to expand the student capacity without committing more resources. The Gray Eagle course is just beginning, and the Hunter course is winding down. There is enough infrastructure for the planned capacity. Any expansion would require more resources.

Training and Training Facilities

Most UAS training operations take place at the Black Tower complex. Gray Eagle and Warrior Alpha vehicles are flown out of Libby Army Airfield.

Military and General Support Mission

Fort Huachuca is home to the military intelligence schoolhouse. This proximity could provide a unique opportunity for collective training between the two schoolhouses. Huachuca is also home to the Buffalo Soldier Electronic Testing Range.



Weather

Fort Huachuca has excellent weather for UAS operations. It has approximately 270 training days a year.

Location

See Figure C.3. Fort Huachuca is situated in southeastern Arizona, near the town of Sierra Vista. There are approximately 60,000 people at Fort Huachuca.

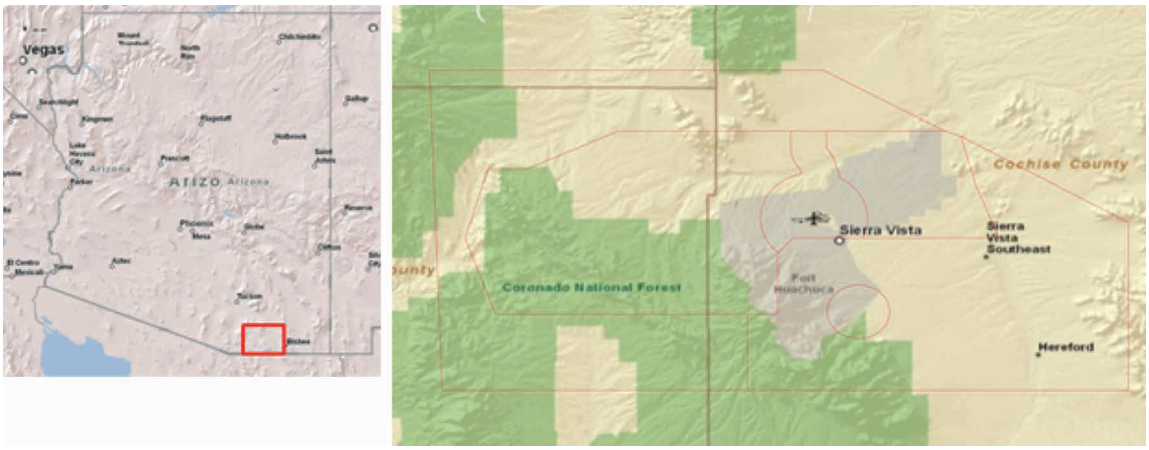


Figure C.2
Airfield and Maintenance Facilities at Fort Huachuca

RAND *RR440-C.2*

4656 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

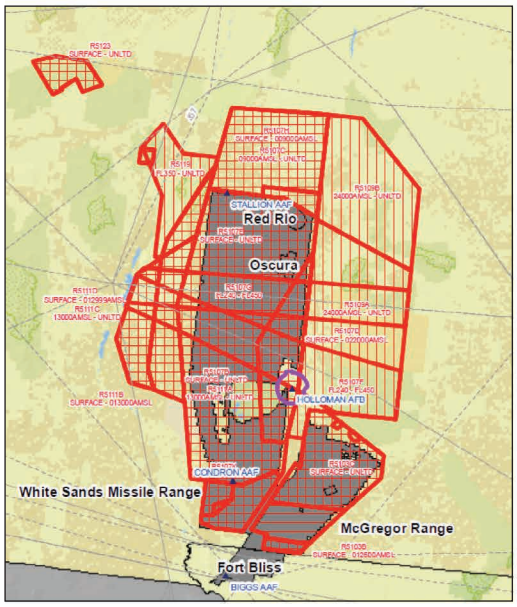
Figure C.3
Location of Fort Huachuca

RAND *RR440-C.3*

Base Loading

Fort Huachuca is the hub for Army UAS training. This consolidation could be both good and bad. The lack of redundancy elsewhere limits the ability to expand operations when needed. For example, if one of the runways were damaged, the entire Army UAS training capability could be severely affected.

Air Force Active Duty MQ-1/9 Formal Training Unit—Holloman AFB, New Mexico



Flight Training Areas and Airspace

See Figure C.4. Holloman AFB has access to the restricted airspace areas within the White Sands Missile Range (WSMR) and McGregor airspace. It is possible to reach both ranges without leaving restricted airspace. While competition for airspace is fierce, WSMR supports flying RPA operations out of Holloman AFB. The current plan is for MQ1/MQ9 to depart Holloman AFB northbound for WSMR airspace and to remain totally within R-5107 B/C/D/H. An alternative is to depart Holloman AFB southbound and climb to FL-180 in R-5107D. There is a three-way memorandum of understanding in place, but the testing mission at WSMR occasionally conflicts with RPA training. A few other areas near Holloman AFB have potential for RPA operations, although they require COAs from the FAA.

The MQ-1/9 FTU completed the transition from Creech AFB to Holloman AFB. Plans call for an additional FTU, bringing a total of five MQ-1/9 training squadrons, including one maintenance squadron, to Holloman AFB. These squadrons will fall under the 49th Wing and bring in an additional 200 officers, 250 enlisted, and 150 contractors. Two hundred students are expected to cycle through in three-month training periods. Holloman AFB would have 28 MQ-1s and 10 MQ-9s. To operate the aircraft, they would have 12 common ground stations, four Predator Primary Satellite Links, two LREs, and five mission control elements. They expect to fly approximately 2,800 sorties a year, 540 at night.

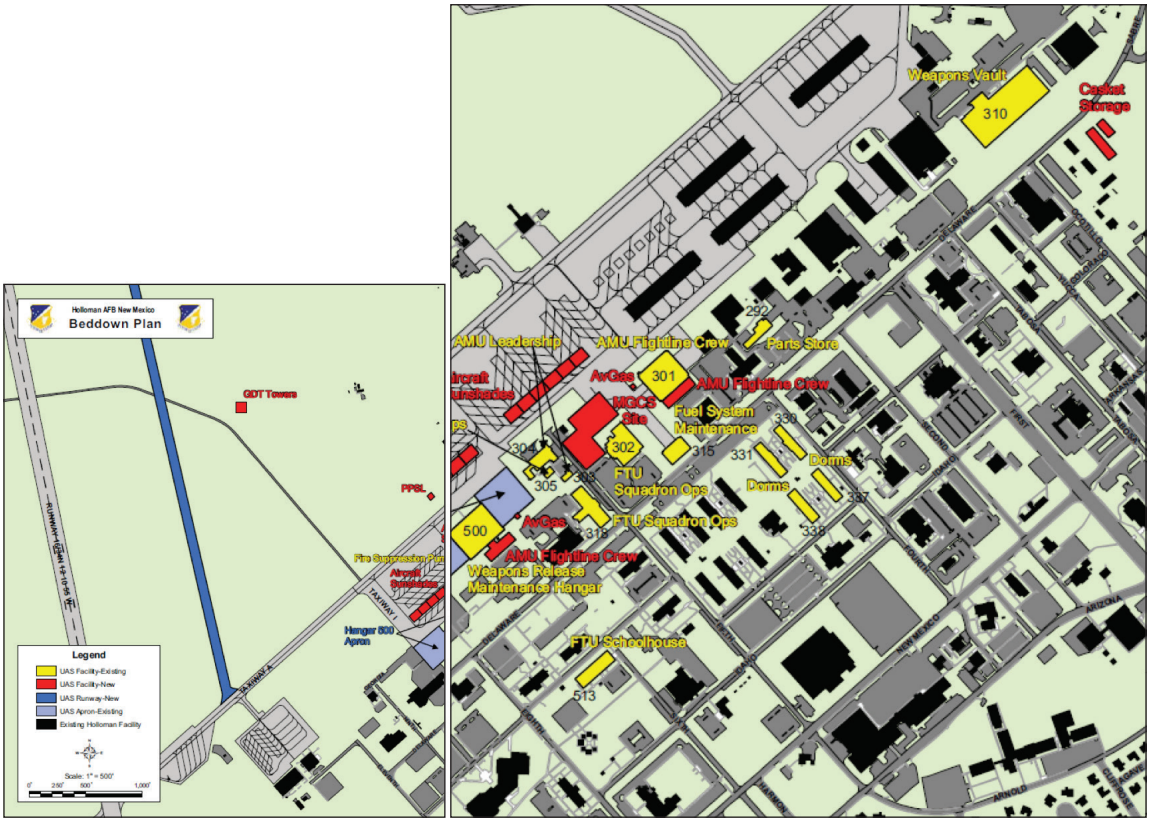
RAND *RR440-C.4*

Airfield and Maintenance Facilities

These are included with the training facilities.

Expansion Potential

The second MQ-9 FTU is scheduled to open in FY 2013, making Holloman home to three MQ-1/MQ-9 FTUs. There is currently a year lag in infrastructure to be able to support a third FTU. The new facilities were supposed to have been finished prior to the standup of the new FTU; however, construction is running approximately a year behind schedule. It is difficult to comment on the ability to meet the required capacity as the capacity requirement is in flux.



Training and Training Facilities

See Figure C.5. Holloman AFB has 200,000 ft^2 of existing and open facilities, including office space and hangars that could accommodate the FTUs with minor renovations. The map in Figure C.5 shows where new facilities would be located and identifies existing facilities.

Table C.1 shows the space required to start up the unit, as well as the required final bed-down space, as defined by military construction. Table C.2 shows the facility plan for each functional requirement.

4658 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Figure C.5
MQ-1/MQ-9 Beddown Plan

RAND *RR440-C.5*

Military and General Support Mission

Other aircraft flown at Holloman currently include the T-38, MQ-1, MQ-9, the QF-4, and the German Tornado.[3] There are plans to move at least a portion of the F-16 FTUs from Luke AFB, Arizona, to Holloman AFB. This could affect the availability of airspace access.

Location

Holloman AFB is located in southern New Mexico, near the town of Alamogordo. The base encompasses about 59,600 acres and has a population of about 21,000 military, civilian, and families.

Base Loading

Moving the FTUs from Creech AFB to Holloman AFB freed up some capacity at the former and allowed the latter to focus purely on training.[4] There is some redundancy with the Air National Guard FTU at March ARB; however, that FTU is much smaller and primarily trains

[3] A German training unit is stationed at Holloman AFB. The F-22s will be transitioning from the base. Air Combat Command and the Air Staff are deciding what to put in place of the F-22 squadron.

[4] The LRE training is a separate course from the FTU and still taught at Creech.

[a] Use maintenance bay.

Air National Guard operators. March ARB currently has adequate infrastructure and capacity for its training mission.

Air Force RQ-4 Formal Training Unit—Beale AFB, California

Flight Training Areas and Airspace

Because of the altitude at which RQ-4s conduct their primary mission, airspace access is manageable at Beale AFB. A cylinder is used to access Class A airspace. The FAA provides a standing window for flights into this cylinder of 10 hours a day, every weekday. Requests outside this window are handled individually and have not been a limitation.

Airfield and Maintenance Facilities

Beale AFB has dedicated airfield and maintenance facilities.

Expansion Potential

There is enough capacity for expanding the training mission of RQ-4s at Beale AFB. There are plans to include some portion of the operator or maintenance training for the Navy's MQ-4 BAMS at Beale, but this would be several years from now.

Maintenance hangar (new FTU)	Use building 500.
Maintenance hangar (3 FTU squadrons)	Use building 301.
FTU squadron operations (new FTU)	For initial capability, use building 513 and a portion of building 302; when project is complete, transition from building 513 into building 318.
FTU squadron operations (Creech UAS)	If there are two FTU squadrons, use building 318; a third FTY squadron can occupy all of building 302 after F-22A transition is complete.
Aircraft maintenance unit (new FTU)	Initially locate leadership team in building 303 and operate flightline crews out of building 301 until completion of building 500 new construction (10,000 ft^2).
Aircraft maintenance unit (3 FTU squadrons)	If two units, locate both leadership teams in building 303 and flightline crews of the second unit in building 301. If three units, locate third leadership team in building 302 and locate flightline crew in building 302. New construction for building 301 can also be considered for the third crew.
Fuel system maintenance	Use building 315.
Precision guided munitions facility	Construct two maintenance bays and administration.
Munitions storage	Construct 26-by-120-ft Hayman igloo (possibly two 60-ft sections).
Aircraft parts store (new FTU)	Use existing contract support or shared building 292 (T-38 parts store).
Aircraft parts store (3 FTU squadrons)	If T-38 mission relocates, use building 292. If no relocation, add space to building 292.
Weapon release shop	Use each respective maintenance bay (building 500 for one and building 302 for two).
Casket storage	Construct 50-by-800-ft covered storage pad in logistics readiness squadron yard. Requirement may grow, depending on quantity of MQ-9 caskets on hand.
Bulk fuel storage	Construct two 8,000-gallon tanks adjacent to hangars 301 and 500 (for aviation gas) for MQ-1 and use existing JP-8 capacity for MQ-9.
Various backshops	Construct 5,000-ft^2 addition on building 500. Building 301 may require new additional space.

Training and Training Facilities

Beale AFB has adequate training space. There are several different aspects of training: classroom, simulation, and live flights. There is enough classroom space available for both the sensor operator training and the pilot training. The pilots use a pilot simulator to cover emergency procedures and aircraft operation. This simulator is very limited in its ability to mimic real-life contingencies. The sensor operators train on Data Analysis Workstations. These two simulators are not compatible, so there is no true crew simulator. Such a simulator has been

4661 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Figure C.6
Location of Holloman AFB

RAND *RR440-C.6*

programmed but is still eight to ten years away.[5] Crew training takes place on live missions, with instructors flying the mission with students.

Military and General Support Mission

Beale AFB is home to several other aircraft, including the MC-12, the U-2, and the T-38. The RQ-4 fits well with the mission of other aircraft at Beale since it was designed to eventually replace the U-2. RQ-4 pilots are also doing tours in the MC-12. There was some talk of maintaining dual currency in the two platforms, but the status of that plan is unknown.

Location

Beale AFB is located in northern California, approximately one hour outside Sacramento. The nearest town is Marysville, California.

Base Loading

Beale AFB is the hub for high-altitude surveillance. The installation is extremely large, with plenty of room for growth.

[5] We understand this decision to be based on resources since on-the-job training on live missions is available.

4667 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Unmanned aircraft systems (UASs) have become increasingly prevalent in and important to U.S. military operations. Initially serving only as reconnaissance or intelligence platforms, they now carry out such other missions as attacking enemy forces. The swift expansion in their numbers and in the demand for their employment has, however, significantly increased demands on logistics and training systems. The challenge is not simply training system operators but also training operational forces and their commanders to integrate the systems into combat operations. Much of that aspect of training has thus far happened as units employ the systems in actual operations—essentially, on-the-job training. UAS training, particularly for the employment of UASs, now needs to be integrated more formally and cost-effectively into service and joint training programs. This report develops a general concept for training military forces in employment of UASs and a framework for addressing the training requirements and discusses the limits of existing infrastructure in supporting UAS training. Interoperability among services is another issue, because services have thus far mainly developed training suitable for their own needs. But the services have established a set of multiservice tactics, techniques, and procedures for UASs, which should facilitate interoperability training. At present, units are not always ready for joint training, so the focus should be on improving training at the unit level in the employment of UAS capabilities, with the overall guiding principle being to "train as we fight."

14. ABSTRACT

Unmanned systems have become a vital component of US military operations in the twenty-first century. They are here to stay, and their utility will continue to expand. Nevertheless, uninformed beliefs and biases continue to skew the discourse regarding unmanned systems. These systems do not constitute a fundamental change in the nature or character of warfare. Policymakers, strategists, or operators who attempt to use unmanned systems in place of human prudence will be profoundly disappointed with the results. They are not a revolution in military affairs, nor do they provide easy answers to the challenges of war. While all of the Services have developed and fielded unmanned systems, the US Air Force's evolution of unmanned aircraft since 2001 is particularly illuminating for future endeavors.

Rather than pursue robotic autonomy, the US military must cultivate professional service members with the skill and discipline to wield unmanned systems adeptly. The Services must fully integrate the tactics and technology of unmanned systems with manned components of the force, as both will be crucial in future endeavors. Leaders should never allow technology to dictate policy or strategy; unmanned systems must always fit into legitimate and comprehensive plans.

ABSTRACT

UNMANNED SYSTEMS IN PERSPECTIVE, by Major David F. John, United States Air Force, 94 pages.

Unmanned systems have become a vital component of US military operations in the twenty-first century. They are here to stay, and their utility will continue to expand. Nevertheless, uninformed beliefs and biases continue to skew the discourse regarding unmanned systems. These systems do not constitute a fundamental change in the nature or character of warfare. Policymakers, strategists, or operators who attempt to use unmanned systems in place of human prudence will be profoundly disappointed with the results. They are not a revolution in military affairs, nor do they provide easy answers to the challenges of war. While all of the Services have developed and fielded unmanned systems, the US Air Force's evolution of unmanned aircraft since 2001 is particularly illuminating for future endeavors.

Rather than pursue robotic autonomy, the US military must cultivate professional service members with the skill and discipline to wield unmanned systems adeptly. The Services must fully integrate the tactics and technology of unmanned systems with manned components of the force, as both will be crucial in future endeavors. Leaders should never allow technology to dictate policy or strategy; unmanned systems must always fit into legitimate and comprehensive plans.

ACKNOWLEDGEMENTS

I would like to thank Dr. Bob Tomlinson for his flexibility and patience as my monograph director. He allowed me the freedom I needed to explore this subject while still providing sage and timely guidance to keep me on track. I earnestly hope that the final product reflects this mutual trust. I am also indebted to Col Uwe Jansohn for his mentorship. His advice and his example have taught me a great deal about leadership at the field grade level and above.

To the instructors and graduates of the 26th Weapons Squadron, whose research and recommendations invigorated much of my thesis, and to the RPA instructor pilots who reviewed my drafts: I am grateful for your assistance and honored to be a member of your community. What we do and say profoundly affects the future of the Air Force. We have to get this right, and based upon your examples, I know that we will.

Deepest thanks go to my family, whose painstaking reviews helped to make my prose legible to a broader spectrum of readers than folks who wear green pajamas to the office. Chief among these is my wonderful wife. Her tireless efforts as a brand-new mother to our son provided me with the maneuvering space I needed to complete this project despite the (blissful) cacophony of novel sounds and duties.

INTRODUCTION

Technology alone has never won a war. Genghis Khan's stirrups, Hernán Cortés's firearms, and America's atomic bombs all gave their users critical advantages, but they were pivotal only because they fit into situations and strategies that suited their use. Unmanned systems today fall into the same category. Though many see so-called "drones" as a revolutionary, ominous development in warfare, in fact they are nothing of the sort. Unmanned systems do not constitute a fundamental change in the nature or character of warfare. Policymakers, strategists, or operators who attempt to use unmanned systems in place of human prudence will be profoundly disappointed with the results.

Two explanations exist for the burgeoning interest in military unmanned systems over the past decade. The first is the most obvious: they are multiplying across the globe. Advances in technology, cost considerations, and persistent conflicts waged by modern societies fuel this proliferation. Unmanned systems satisfy numerous requirements for policymakers and combatants. Their utility will continue to expand.

The second explanation for the prevalence of unmanned systems in public discourse is more subjective—they impassion people across a wide spectrum of beliefs and interests. Engineers envision marvelous new creations. Futurists and philosophers contemplate the implications of autonomous robots. The defense industry sees a profitable market. Military budgeters imagine billions of dollars in savings. Commanders clamor for solutions to extend their situational awareness (SA) and control of the battlespace.[1] Soldiers, sailors, airmen, and Marines

(and their loved ones) envision war without friendly casualties. Meanwhile, pacifists proclaim that drones are slaughtering innocents, and conspiracy theorists think the movie *The Terminator* is now a reality.[2]

In other words, assertions about unmanned systems often depend more on a speaker's beliefs than on the facts, and these biases distort the collective discussion. The critical thinker must endeavor to minimize these inevitable shades, but one cannot eliminate them. The following analysis just as surely reflects the author's own biases. He is a United States Air Force (USAF) senior pilot of both manned and unmanned aircraft, and holds dual master's degrees in military history and military operational art and science. This background suggests an opportunity for contextual accuracy that many voices in the debate may lack.

This project consists of five parts. Section I examines the evolution of unmanned systems into the types currently employed by the US military. Section II analyzes the ways in which the USAF has integrated unmanned aircraft systems (UAS) into the modern battlefield.[3] Section III addresses the false notion that unmanned systems are a revolution in military affairs (RMA), and debunks flawed assumptions regarding the development and employment of this technology. Section IV delves into the realm of policy to demonstrate that unmanned systems change neither the nature nor the rules of armed conflict. Finally, Section V presents three recommendations for the further development and operation of military unmanned systems: professional discipline, comprehensive integration, and prudent strategy.

The lexicon surrounding unmanned systems remains in a state of flux (so it goes with military jargon). This project will adhere to the terminology contained within Joint Publication 1-

[3]The term Unmanned Aerial Vehicle (UAV) refers to an aircraft per se, while Unmanned Aircraft System (UAS) denotes the collection of components that make up a complete package, to include aircraft, control station, launch and recovery equipment, communications relays, etc.

4678 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

02 and the Department of Defense (DOD) *Unmanned Systems Integrated Roadmap FY2011-2036*, but direct quotes will preserve authors' original phrasing and abbreviations. The expression "unmanned system(s)" will remain unabbreviated throughout this discussion. The inaccurate and pejorative term "drones" will appear only by exception.

I – UNMANNED SYSTEMS PAST AND PRESENT

Humanity has been on a quest to increase standoff distance in warfare ever since an early hominid first thought to hurl a rock instead of bludgeoning his enemy. While the intercontinental ballistic missile (ICBM) and its younger sibling the cruise missile are the ultimate weapons in distance warfare, the military technically does not regard them as unmanned systems. The *Unmanned Systems Safety Guide* defines an unmanned system as such:

> An electro-mechanical system that is able to exert its power to perform designed missions and includes the following: (1) there is no human operator aboard and (2) the system is designed to return or be recoverable. The system may be mobile or stationary. [Unmanned Systems] include unmanned ground vehicles [UGVs], unmanned aerial vehicles [UAVs], unmanned underwater vehicles [UUVs], unattended munitions, and unattended ground sensors. Missiles, rockets and their submunitions, and artillery are not considered [unmanned systems].[4]

The development of unmanned systems spanned the twentieth century. In 1898, Nicola Tesla built a radio-controlled boat, which he envisioned as a potential weapon. Western militaries developed remote-controlled aircraft and torpedoes during World War I, but none proved particularly successful.[5] Further development occurred during the interwar years but reliability and accuracy remained problematic. During World War II, Japan experimented with unmanned air, sea, and ground vehicles, but ultimately it addressed the accuracy problem by resorting to the kamikaze. Germany actually deployed several thousand UGVs called *Goliath*, but their slow

speed, unwieldy cable link, and lack of a camera (forcing operators to remain within eyesight) made them impractical in combat.[6] The Allies remained largely disinterested in unmanned systems during the war, notwithstanding the tragic crash of an experimental remotely controlled B-24 bomber that claimed the life of Joseph P. Kennedy Jr., the future president's older brother.[7]

Following World War II, the US military's interest in unmanned systems began to grow. The US Navy used unmanned maritime systems (UMS) to conduct minesweeping operations and to take radioactivity samples after nuclear tests.[8] In the late 1960s, the USAF first experimented with manned-unmanned teaming by remotely controlling AQM-34 UAVs from an airborne C-130 aircraft.[9] Most UAVs during the Cold War flew as practice targets, as decoys for enemy radars, or for limited intelligence collection.[10] Concurrently, the US military made great strides with precision-guided weapons and satellite technology, both of which proved crucial to future unmanned endeavors.[11]

The 1990s heralded the modern age of unmanned systems with the arrival of the General Atomics RQ-1 Predator, which flew reconnaissance missions over the conflicts in the Balkans from 1995 onward.[12] The National Defense Authorization Act of 2001 gave the DOD the goal to

convert one third of its deep strike aircraft into unmanned systems within a decade.[13] In the first half of 2001, the US military began test firing AGM-114 Hellfire missiles from Predator aircraft.[14] The anti-tank Hellfire's lightweight design, laser-guided precision, and modifiable warhead made it a flexible weapon for a wide array of potential targets.

The events of 11 September 2001 (i.e. 9/11) accelerated the weaponization of unmanned systems. On 7 October 2001, the United States first flew an armed Predator over Afghanistan,[15] and on 4 February 2002, a Predator launched the first Hellfire in combat. The alleged target was a tall Saudi expatriate wanted for the recent murder of 3,000 American civilians. The identification proved erroneous, and Osama bin Laden survived for another nine years before his death at the hands of US Navy SEALs.[16] By the end of the first year of Operation Enduring Freedom, Predator crews had launched Hellfires at 115 targets in Afghanistan.[17]

In December 2002, the USAF conducted an on-the-job experiment with unmanned air-to-air combat by loading AIM-92 Stinger missiles on its Predators flying over Iraq. One Predator fired a Stinger at an attacking Iraqi MiG-25 fighter, but it missed—the MiG did not.[18]

Unmanned Aircraft in the US Military

The Predator is the best-known UAS, but it is only one of many unmanned systems currently flying over conflict zones. The growth of UAS in the past two decades brings to mind the development and proliferation of manned aircraft in the years immediately prior to and during World War II.[19] In the United States, the late 1930s and early 1940s saw the progression of fighter aircraft from outdated monoplanes into the venerable P-51 Mustang and jet prototypes, while twin-engine bombers paved the way for the mighty B-29 Superfortress. Likewise, UAS operated by the US military have burgeoned from simple prototypes into a wide array of sizes and capabilities.

The DOD categorizes its operational UAS into five groups.[20] Group 1 consists of short-range unmanned aerial vehicles (SR-UAVs). SR-UAVs in the current DOD inventory are unarmed and communicate via direct line-of-sight (LOS) signals. These platforms, currently flown by all the Services, include hand-launched UAVs like the RQ-11 Raven. The Raven provides "over the hill" situational awareness (SA) to troops in the field. These troops can manually fly the SR-UAV, or program it via Global Positioning System (GPS) waypoints, out to a range of seven to ten miles. Its camera, which sends live video back to the operator, includes both electro-optical (i.e. television) and infrared modes. The WASP III, also known as the Battlefield Air Targeting Micro Air Vehicle (BATMAV), is an even smaller UAV used by Special Operations Command and the US Marines. It has a range of three miles with electro-optical and infrared capabilities similar to the Raven's sensors.[21]

---

[19]Gertler, 6.

[20]Each of the Services groups its UAS into tiered systems that do not always correspond to the other Services' categories; the DOD's five-group methodology is one attempt to rectify this confusion.

4682 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Group 2 consists of the Scan Eagle, an albatross-sized UAS launched via catapult, to include mounts on US Navy ships. The Scan Eagle can fly via preprogrammed waypoints out to sixty miles for up to twenty hours. The Navy and Marines plan to replace their Scan Eagles with a new Small Tactical Unmanned Aerial System (STUAS), with similar real-time intelligence, surveillance and reconnaissance (ISR) capabilities.[22]

Group 3 contains the slightly larger RQ-7 Shadow and the MQ-5 Hunter. These UAS fly higher, faster, longer, and farther than the UAS in Groups 1 and 2, but they remain tethered to a LOS data link.[23] While the RQ-7 is unarmed, the US Army has equipped several of its MQ-5s with small laser-guided bombs (the "M" designates multi-role, i.e. weapon carrying, versus the unarmed "R," for reconnaissance).[24]

Group 4 is the domain of the MQ-1 (formerly RQ-1) Predator. It can carry up to two Hellfire missiles and pilots can fly it using LOS signals or via satellite communications (SATCOM). Because SATCOM introduces approximately a two-second roundtrip delay between an operator's input and the visible aircraft response, USAF crews launch the Predator via LOS. They then transfer control to a geographically separated crew that uses SATCOM to fly missions that can last over twenty-two hours. Remote split operations (RSO) is the term for this collaboration.[25] Also included in Group 4 is the US Army's MQ-1C Gray Eagle, a Predator variant that the Army continues to improve and field in greater numbers, and the MQ-8 Fire Scout unmanned helicopter.[26] The latter currently is in testing to carry small laser-guided

rockets.[27] The Navy's Unmanned Combat Air System (UCAS), presently in the initial stages of development, will be the subject of further analysis below.[28]

Group 5 consists of the largest UAS in today's inventory: the MQ-9 Reaper, RQ-4 Global Hawk, and RQ-170 Sentinel. The Reaper is essentially the Predator's big sibling. It can carry up to 3,000 pounds of weapons, currently a combination of Hellfires and 500-pound laser- or GPS-guided bombs. It also can mount payloads like synthetic aperture radar, wide-angle cameras, and other signals intelligence (SIGINT) equipment.[29] Reapers eventually will supplant Predators in the USAF inventory, though the timing of this phased replacement remains in flux.[30]

Dwarfing the Reaper is the RQ-4 Global Hawk, which boasts a 130-foot wingspan. It is significantly larger than the U-2 spy plane of Cold War fame that it was designed to replace (both aircraft remain in service today). The RQ-4 has a 60,000-foot ceiling, 28-hour endurance, a range of 8,700 miles, and cruises at over 300 knots using a turbofan jet engine.[31] In 2001, one flew nonstop from the United States to Australia.[32] The Global Hawk uses RSO similar to the Predator and Reaper, though pilots typically fly it using preplanned autopilot routes rather than manually.[33] The unarmed Global Hawk's missions are ISR and battlefield communication support.[34]

4684 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The United States acknowledges the existence of the RQ-170 Sentinel, but details of the program remain mostly classified.[35] The RQ-170's "flying-wing" design resembles a B-2 bomber. It has a sixty-five-foot wingspan and a single jet engine. Reports claim an RQ-170 provided ISR and data relay for the US Navy SEAL raid that killed Osama bin Laden in Abbottabad, Pakistan, on 1 May 2011.[36] In December 2011, Iran's government claimed that it downed an RQ-170 after the aircraft violated Iranian airspace, but details of the incident remain unclear.[37]

Although many voices in the UAS community continue to advocate for a future of boundless technological expansion, American UAS growth and development is slowing. As late as 2009, the USAF's *UAS Flight Plan* included a timeline for the development of autonomous aircraft, lethal miniature "swarming" robots, unmanned refueling aircraft, three types of advanced tactical UAS, and next-generation long-endurance ISR platforms.[38] Fiscal constriction and the United States' withdrawal from Iraq and drawdown in Afghanistan have forced the DOD to reorient its vision for unmanned systems toward more realistic objectives. In 2009, it cancelled an advanced satellite project to improve military SATCOM bandwidth.[39] The Fiscal Year 2013

defense budget halted procurement of new USAF Global Hawks (energetic lobbying is likely to restore funding for the program in the 2015 budget, however).[40] The DOD has slowed the acquisition of Reapers and delayed the Predator's retirement to cover the shortfall.[41] The USAF has canceled plans for a stealthy "MQ-X" and halted progress on further medium-sized UAS designs.[42] The Defense Advanced Research Projects Agency (DARPA) continues to promote UAS research and development, but for the time being the true driver of military technology—defense appropriations—is decelerating.[43]

Unmanned Ground Systems and Mission Command

The US Army had big plans for unmanned ground systems (UGS). In October 1999, the Army began work on a three-decade modernization known as the Future Combat System (FCS). This project envisioned a network of "manned, unmanned, and robotic" vehicles and support equipment designed to enable the Army to prevail on modern and future battlefields.[44] The unmanned projects in the FCS included several variants of UGV, unattended ground sensors, and two new UAVs: a hovering miniature air vehicle and a Fire Scout variant.[45] The most novel technology was an armed UGV, operated remotely, which could be equipped with a wide array of

4686 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

lethal (and nonlethal) payloads.[46] While the production model remained in development, in 2007 the Army actually deployed three armed prototypes of the Talon UGV, called SWORDS (Special Weapons Observation Reconnaissance Detection System), to Iraq.[47] The Army appeared on the verge of a major shift toward reliance on unmanned systems, to include lethal UGS.

A decade of sustained land combat and significant program setbacks led to the demise of the FCS before any of its revolutionary unmanned systems ever hit the field. While Soldiers battled irregular insurgents and improvised explosive devices (IEDs) in Iraq and Afghanistan, the FCS program suffered repeated delays and cost overruns. In April 2009, Defense Secretary Robert Gates began dismantling the FCS program by recommending the cancellation of its manned ground vehicle.[48] In January 2010, the Army stopped procurement of the larger UAV, followed by the demise of the smaller one in early 2011 (though several dozen prototypes did see service in the field). Then it stopped development of the unattended ground sensors. Finally, it canceled the UGV.[49] The SWORDS prototypes that deployed to Baghdad never fired a shot, and the Army chose not to purchase more of these systems.[50]

Cost overruns tarnished the FCS, but the program's demise also stemmed from a conscious decision by the US Army and Marines to move away from technological solutions in favor of human ones. These Services have reoriented their focus toward "mission command," the concept of empowering commanders and subordinates to exercise disciplined initiative,

4687 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

underpinned by shared understanding and mutual trust.[51] This philosophy is fundamentally about human minds and decision-making, but unmanned systems do still factor into its implementation. FCS-envisioned networking capabilities continue to make progress, improving mission command on the battlefield.[52] The military also continues to experiment with UGS as an extension of—not a replacement for—human capabilities. Spatial disorientation, task saturation, and frequency congestion in crowded urban environments remain problematic when remotely controlling ground vehicles.[53] Nevertheless, numerous UGS prototypes have made their way into the hands of deployed troops, who have developed innovative methods to use them. The initiative of these Soldiers and Marines exemplifies the mission command philosophy.

The Army's most beloved unmanned systems are the UGVs it uses for explosive ordnance disposal. Remote-operated Talons, as well as a smaller vehicle called the PackBot, have saved countless lives—both military and civilian—by defusing IEDs and other explosives that formerly required human technicians to neutralize them.[54] The US military has used between 5,000 and 6,000 UGVs to defuse tens of thousands of IEDs in Iraq and Afghanistan.[55]

The Army is also fielding a 5.5-pound UAV known as the Switchblade, which sports a grenade-sized warhead designed for precision engagement of small targets.[56] Medea Benjamin of Code Pink calls it a "robotic suicide bomber . . . an unmanned kamikaze."[57] She fails to account for the fact that a human remains in control of its maneuvering and lethal employment. In context, the Switchblade sounds far less ominous—and certainly more discriminating—than the ballistic artillery shells responsible for the majority of violent deaths in modern warfare.[58] The Army and Marines will continue to develop unmanned systems, but they do not appear whatsoever interested in relinquishing lethal discretion to autonomous robots.

Unmanned Maritime Systems

The US Navy's recent experience with unmanned systems is similar to that of the Army: while a massive modernization program flounders, discreet technologies are finding their way into operational use. In 2002, the Navy began a program to develop and field an advanced warship called the Littoral Combat Ship (LCS). The Navy wanted the LCS for combat operations in coastal regions. Designers promised an affordable, modular solution to difficult problems like minesweeping, detection of stealthy submarines, and defense against small-boat threats.[59] The Navy planned to use a plethora of unmanned systems to enable a drastic reduction in LCS

crewmembers: just forty Sailors per ship, as opposed to over three hundred on a modern cruiser.[60] The LCS would deploy unmanned surface vehicles (USVs), unmanned underwater vehicles (UUV), and UAS including the Fire Scout helicopter.[61] The Navy originally asked for seventy LCS hulls, but ultimately settled on fifty-two.[62] Two competing ship designs, one from Lockheed Martin and the other from General Dynamics/Austal, began concurrent development. As the LCS program got underway, worldwide contingency operations prompted a number of smaller experiments under real-world conditions.

During the 2003 Iraq War, the Navy deployed the Spartan Scout, a remotely operated USV equipped with sensors and communication gear, to inspect civilian boats in the Arabian Gulf.[63] Unmanned seaborne operations proved more challenging than airborne ones for many reasons. Ship-mounted antennas limited LOS range for remote surface operations to roughly six nautical miles, although SATCOM capabilities or a relay vehicle could mitigate this shortcoming.[64] Autonomous USVs might use GPS to maneuver at greater range, but without a link to the ship, their utility would be limited. Roiling seas, adverse weather, and corrosive saltwater wreaked havoc on sensitive technology.[65] One Navy study determined that USVs were

more manpower-intensive than manned vessels due to their many intricate systems.[66] Spartan Scout testing ended in 2006, whereupon further USV research became part of the LCS program.[67]

Another unmanned system that made its military debut in 2003 was the Remote Environmental Monitoring Unit, or REMUS. This torpedo-shaped UUV, adapted from an existing civilian model, conducted minesweeping operations in the Arabian Gulf harbor of Um Qasr.[68] Its preprogrammed movements and navigation sensors alleviated the need for a cable link to send commands, meaning it truly acted autonomously. Like the Spartan Scout, REMUS was a precursor to equipment that will be integral to the LCS and other naval vessels in the future.

While Sailors and Marines have spent the last decade experimenting with unmanned systems under combat conditions, the LCS program has become a quagmire. Originally promised at $220 million each, the Fiscal Year 2012 budget listed the per-unit cost of an LCS at over $1.8 billion.[69] The first two prototypes arrived two years behind schedule.[70] Minesweeping modules are four years late, with estimated completion in 2017.[71] The ships will not finish full operational testing until 2019 at the earliest.[72] Poor management, requirements creep, and real-world developments have hamstrung the LCS program.

The problems with the LCS point to a broader conclusion: at present, unmanned systems cannot replace most humans at sea. One of the costliest modifications to the LCS has been a twenty-five percent increase in crew size to alleviate workload and fatigue, and this number is likely to increase.[73] Space aboard the LCS is tight: if crew requirements grow too large, the viability of both competing ship designs may come into question. Tests on several of the LCS's unmanned systems have revealed unacceptable failure rates and unforeseen complications that corroborate the increased staffing requirements for the Spartan Scout USV.[74] In July 2013, the Government Accountability Office issued this scathing pronouncement: "Current LCS weapon systems are under-performing and offer little chance of survival in a combat scenario."[75] Unlike the Army's defunct FCS, the LCS continues to survive on life-support, but the future of the program remains uncertain. In the meantime, the Navy is pursuing one more noteworthy foray into the world of unmanned systems.

The Navy currently operates proven UAS of many shapes and sizes, but it also is developing and testing a potential game-changer: the X-47B UCAS.[76] The Navy adapted its design from a joint UCAS program that the DOD cancelled in 2006.[77] The stealthy X-47B has a sixty-two-foot wingspan (comparable to a Reaper or an RQ-170), uses jet propulsion, and includes weapons bays for up to two 2,000-pound bombs.[78] On 14 May 2013, the X-47B made its first successful catapult launch from the deck of the U.S.S. *George H.W. Bush* (it landed ashore,

as planned). Two months later, it made its first carrier landing.[79] Concurrently, the Navy began testing unmanned aerial refueling from manned tanker aircraft, using a Learjet modified for autonomous flight with human pilots onboard to override any glitches.[80]

The Navy plans to grant unprecedented levels of autonomy to the X-47B. Although current tests involve multiple redundant human controls (pilots, deck officers, and tower personnel all have the ability to wave-off the aircraft from a bad approach), ultimately the Navy envisions a UAS that can fly missions all on its own.[81] However, as Captain Jaime Engdahl, the UCAS program manager, confesses: "We are in the crawl-walk-run stage of autonomous systems."[82] The Navy is emphatic that the UCAS is simply a demonstration, and a limited one at that. Originally, it planned to retire the X-47Bs after the July carrier tests. Under pressure from politicians and the defense industry, the Navy conceded to continued experiments. It has allocated a further $20 to $25 million to keep the program alive while it determines how to proceed.[83] The Navy does not anticipate fielding an operational X-47B before 2019.[84]

Accompanying the Navy's embryonic experiments with autonomy is the notion that a carrier-based, stealthy UCAS could alleviate host-nation basing requirements for UAS. Elimination of forward bases might reduce the perceived need to gain foreign approval for combat operations.[85] Then again, USAF B-2 bombers (which fly intercontinental missions from

Missouri), carrier-launched manned aircraft, and other ISR assets have conducted military operations without basing rights for decades.

Despite various methods of controlling unmanned systems, a human remains "in-the-loop" and responsible for their safe operation at all times (with the exception of the innocuous REMUS UUV). No autonomous robots are out conducting combat missions unsupervised while their human monitors leave the controls for a lunch break. More importantly, humans remain entirely in charge of every decision to launch lethal munitions, just as they do in manned platforms. While the Army and Marines operate most unmanned systems as an additional duty for conventional troops, the USAF requires rated pilots to fly its Group 4 and 5 platforms.[86] The next section will discuss how these airmen employ UAS in today's conflicts. While all of the Services continue to develop tactics, techniques, and procedures (TTP) for unmanned systems, the USAF's experience over the past twelve years provides the clearest assessment of the realities of unmanned systems in modern warfare.

II – AVIATORS AND INNOVATORS

The USAF calls its unmanned systems Remotely Piloted Aircraft (RPAs) for a reason. The airmen who fly these platforms are no "cubicle warriors": while they are not physically located inside their airframes, they are connected intimately to the battlefield. Over the past decade, determined RPA crews have toiled to integrate new capabilities into the complex and

According to AFI 11-401, "A rated aircrew member is a commissioned officer who holds a USAF aeronautical rating. The USAF considers rated officers to be in career aviation status and awards ratings only to pilots, RPA pilot, CSOs [Combat System Operators], ABMs [Air Battle Managers], observers, and flight surgeons." See AF/A3O-AT, Air Force Instruction 11-402, *Aviation and Parachutist Service, Aeronautical Ratings and Aviation Badges* (13 December 2010, certified current 5 February 2013), http://www.e-publishing.af.mil (accessed 1 March 2014), 129.

4694 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

evolving battle spaces of America's conflicts.[87] They have managed this feat despite a tempo of constant surge operations, 24 hours a day for 365 days a year. Many RPA crewmembers have deployed to active combat zones to conduct LOS launch and recovery operations.[88] Their innovations have produced remarkable advances in the way the USAF supports the achievement of strategic objectives, operational successes, and tactical victories.

RPAs have become indispensable assets for US military operations. Stated succinctly, "RPAs benefit from a long loiter time, the ability to provide armed over watch and armed reconnaissance with precision-guided munitions, extensive reach-back capabilities, and the ability to have the [full-motion video] FMV feed exploited real-time."[89] They are ideal for military missions including ISR, interdiction, close air support, force protection, and maritime patrol. By replacing low-fuel RPAs with fresh ones and swapping out crews multiple times per sortie, squadrons can extend their persistence indefinitely. While pilots and sensor operators handle the immediate tactical tasks, analysts worldwide simultaneously work round-the-clock to convert FMV and sensor reports into actionable intelligence. RPAs also benefit from low acoustic

[87]For the remainder of this discussion, the term "RPA crew" will refer to the rated pilot, enlisted sensor operator, and mission support personnel in direct support of a particular aircraft. They represent only the spearhead of up to 170 people who can be involved in the maintenance and exploitation of a single RPA. See Gertler, 26.

[88]Depending on the scale and intensity of operations, up to one tenth of a typical RPA squadron is deployed for launch and recovery operations at any given time. Major Eric Hendrickson, USAF, e-mail message to author, 8 November 2013.

signatures.[90] Audible concealment is vital for lethal engagements, but it also aids in the building of comprehensive SA that often leads to a decision *not* to use deadly force.[91]

These capabilities did not arrive overnight. The rapid deployment of immature UAS technology into dynamic war zones following 9/11 complicated the command, control, and coordination of RPAs with other assets. The operational-level Air Operations Center (AOC) repeatedly clashed with tactical personnel in-theater over RPA allocation and tasking. Many times, manned aircraft and joint terminal air controllers (JTACs) had no idea an RPA even was in their vicinity, much less whether it could assist in an active mission.[92] As one expert RPA pilot noted, problems arose from "incomplete understanding of MQ-1/-9 capabilities and systemic perception of RPAs as the 'just-in-case' tactical employment option."[93] These growing pains reprised the US military's repeated battles over the use of airpower at large since World War I.

The USAF's burgeoning RPA community struggled to overcome these deficiencies. The strain of nonstop surge operations initially hampered the development of planning and coordination TTPs to suit remote operations, but these have improved significantly.[94] Networked computer systems, internet relay chat, e-mail, video teleconferencing, and telephones (both secure and unclassified) enable RPA crews to prepare for the geographically separated missions they

face.[95] Nothing can replace face-to-face planning and debriefing, but disjunction is not only an issue for unmanned systems: it is a reality for troops deployed across modern, dispersed battlefields. It also represents nothing new. US Navy aviators have conducted dislocated mission planning at sea for decades. They have developed efficient communications and TTPs that enable them to support distant operations.[96] The RPA community is finally gaining the leeway to free up experienced aviators and intelligence personnel for comprehensive mission planning.[97] This emphasis is critical to optimizing the capabilities RPAs bring to the fight.

Real-time video may be the most coveted asset on RPAs, but their capabilities as a communications bridge are invaluable as well. RPA crews can leverage multiple voice and data links to contact any echelon, from troops-in-contact all the way to national-level authorities. Rather than waiting to return to base in a manned aircraft, an RPA crew can pass immediate, high fidelity mission reports, battle damage assessments, and other in-flight messages to operations centers and commanders. Likewise, they can pass detailed tactical and administrative data forward to other aircraft and ground troops.[98] A rated pilot in the driver's seat puts an "airman's perspective" on tactical messages, thus enhancing their utility to warfighters.[99] Real-time communications are also important for RPA survival: because current models lack onboard threat detectors or countermeasures, crews rely on off-board cues to evade hostile fire.[100]

RPA crews can employ their own Hellfires and laser-guided bombs with surgical precision, but they also can pinpoint targets for manned aircraft with heavier firepower. The persistent, stable perspective of an RPA with multifaceted connectivity is a boon to low-flying

helicopters or fast-moving jets with limited loiter time.[101] An RPA crew may describe visible features in the terrain to guide another aircrew's eyes. The crew also can make use of GPS-derived coordinates, or use the RPA's infrared illuminator or laser designator to cue the sensors of other aircraft, expediting correct target acquisition.[102] The Predator's and the Reaper's lasers are compatible with the targeting pods and laser-guided weapons carried by US (and most allied) aircraft. Use of an RPA to "buddy-lase," in which its laser guides a munition fired from another aircraft or vice-versa, often is the most expeditious and precise method to employ weapons.[103] Ground personnel likewise can use laser designators and infrared pointers to cue aircraft sensors and weapons. Laser guidance also enables an aircrew to shift weapons in flight away from the intended target if noncombatants enter the impact zone or other extenuating circumstances occur—a rare occurrence, since crews thoroughly scan target surroundings before firing.[104]

Tactical data links have become an indispensable component of modern warfare. The RPA community has labored to integrate its aircraft into the primary coalition network, known as Link 16 or the Joint Tactical Information Distribution System (JTIDS). This system communicates position, status, and mission management information regarding friendly assets, detected threats, and potential targets. Link 16 enables diverse platforms to work together across the battle space, increasing SA and enhancing overall effectiveness. These days, an aircraft flying in an active area of operations without Link 16 can be more of a liability than a benefit. Lamentably, RPAs operated in combat zones for years without this essential capability, and this shortcoming hampered their integration with other aircraft.[105] Ultimately, airmen and engineers

devised workarounds to provide basic Link 16 capabilities for Predators and Reapers.[106] USAF RPAs are set to attain full Link 16 capability within a couple years.[107] Future data links must fully include RPAs and other unmanned systems from Day One.

Link 16 connectivity enhances the crucial two-way flow of information needed to maximize the effective integration of RPAs with other assets. When friendly ground troops are nearby, aircrews require clearance from a qualified JTAC or equivalent controller in order to release weapons. Using Link 16, a JTAC can pass digital targeting information to an RPA crew, rather than relying on voice or chat messages (the RPA crew still must visually identify the target and get confirmation from the JTAC before weapons launch).[108] Likewise, a Link 16-equipped RPA with high SA on a target can send detailed information to ground forces and other aircraft instantly and without transmission errors.[109] RPA crewmembers recognize that they are personally responsible for the accuracy and timeliness of target coordinates and information—erroneous or obsolete data could result in fratricide or civilian casualties.[110]

In situations where friendly ground troops do not physically deploy, such as during Operation Unified Protector over Libya in 2011, RPA crews are ideal controllers for strike coordination and reconnaissance.[111] The persistence of an RPA allows crews to build detailed SA over extended periods, as compared to intermittent coverage from manned aircraft following a

---

[106]As initially implemented, RPA positional tracks updated less often than the tracks of full link participants. In addition, all of the aircraft in an RPA squadron operated on a single merged server with one identifier, which necessitated clear, standardized communication procedures to avoid confusion. David M. Martinez, "Digitally Aided CAS in the MQ-1/9" (student paper, United States Air Force Weapons School, 10 December 2011), 2-4, 9; Pederson, 4.

traditional air tasking order. RPAs also can leverage support from myriad coalition assets both inside and outside the theater. An RPA control station can receive cueing information from ISR platforms like the RC-135 Rivet Joint, E-8 JSTARS, E-3 AWACS, U-2, Global Hawk, national-level assets, and tactical aircraft, with scores of analysts in the loop to exploit collected data and intelligence products.[112] Persistent RPAs can pass this SA to arriving aircraft while others depart.

In certain scenarios, RPAs may be the only assets available. Although the USAF initially employed them as single aircraft, RPA crews have developed TTPs to fight as teams. This synergy is similar to manned aircraft flying in formation, but instead of close visual formations, RPA crews can use precise timing and coordination to mass sensors and firepower.[113] This capability is not limited to aircraft from the same squadron. By leveraging the multiple communication methods available in their control stations, geographically separated crews can link up, establish a coordinated game plan, and accomplish a tasking without ever meeting face-to-face.[114] The key to successful execution is the development of shared understanding, based on rigorous training and common tactical standards across RPA squadrons.[115] By practicing and adhering to these innovative TTPs, disciplined crews can transform a few tenuous RPAs into a formidable expression of modern American airpower.

Positive identification of hostile targets in modern combat zones is challenging, but essential.[116] Many enemy combatants do not wear uniforms, and even professional militaries employ deception and camouflage to confuse modern sensors, as the Serbs did by using dummy

tanks during the conflict in Kosovo.[117] Clear, stable FMV from an RPA can be the most important tool in accurately identifying a suspected enemy target. While crews benefit from a team of professional analysts who aid them in making the right decisions, an RPA pilot employing lethal ordnance bears ultimate responsibility for compliance with the rules of engagement (ROE).

In the event of a friendly aircraft crash, an RPA's persistence may be the decisive factor in successful combat search and rescue. MQ-1 and MQ-9 pilots train to act as on-scene commanders for search and rescue, just like other pilots. They can communicate instantly and comprehensively with rescue coordinators at the operations center.[118] Their watchful gaze enables them to direct additional assets to the site—and their precision weapons can target threats to an isolated survivor—without risking additional aircrew.[119] The roar of friendly jet engines, though transitory, may be the ultimate emotional comfort for a downed aviator—but 24-hour overhead cover from an armed RPA realistically offers the best chance for a successful rescue.[120]

III – A REVOLUTION IN MILITARY AFFAIRS?

Definitions abound as to what constitutes a revolution in military affairs (RMA), but the notion of discontinuity is common to all. Andrew Marshall argues that an RMA is "a major change in the nature of warfare brought about by the innovative application of new technologies which, combined with dramatic changes in military doctrine and operational and organizational concepts, fundamentally alters the character and conduct of military operations."[121] An RMA

means more than new gadgets: it represents a fundamental shift that permanently alters the way humans fight. Technology plays a decisive role in nearly all commonly acknowledged RMAs. Specific lists vary, but several episodes tend to feature prominently: the introduction of gunpowder, the Industrial Revolution, the Napoleonic way of war (an exception to the technological impetus), powered flight, blitzkrieg, nuclear weapons, and the Information Revolution of the 1990s.[122] Many believe the time has come to announce yet another RMA.

The Pitfalls of Believing in RMAs

A number of analysts believe unmanned systems constitute an RMA. As P.W. Singer exclaims, "humans' 5,000-year-old monopoly over the fighting of war is over . . . the introduction of unmanned systems to the battlefield doesn't change simply how we fight, but for the first time changes who fights at the most fundamental level."[123] He recalls perusing gadgets in a *Sharper Image* catalog and then reading reports of drone strikes. This juxtaposition convinces him that humanity has arrived at a point of singularity whereupon robots will replace humans on the battlefield.[124] Other writers decry a coming age of "suicide drones," evidently unaware of the irony of the phrase.[125] Admiral Dennis Blair, former US Director of National Intelligence, dismisses the hype. He acknowledges the "novelty factor" of unmanned systems, but believes the

ensuing sense of sinister "overwhelming force" is erroneous.[126] When discussing an RMA, it is critical to examine reality—not to speculate what could theoretically occur. If militaries ultimately imbue robots with the capability and authority to employ autonomous lethal force, then humanity may indeed experience a discontinuity in history.[127] However, that day has not arrived.

The entire RMA concept is misleading because it compartmentalizes and distorts the past, equating newfangled innovations with momentous historical developments. P.W. Singer compares unmanned systems to "fire, gunpowder, the steam engine or the computer."[128] It took humans thousands of years to tame fire. Gunpowder gradually entered the battlefield in an evolutionary process over hundreds of years. Industrial mechanization may have begun in the eighteenth century, but it continues to evolve to this day. Computer technology has progressed exponentially, but its contribution to warfare has not followed a correspondingly inexorable path. Steven Metz explains: "Even in revolutionary times, continuity outweighs change. . . . War will always involve a dangerous and dynamic relationship among passion, hate, reason, chance and probability."[129] True believers in technology would be wise to heed his insight.

RMA proponents of the 1990s focused on new information technologies, like GPS and networking, that helped the United States and its allies defeat Iraq in 1991, but they downplayed the significance of context. Decades beforehand, General William Westmoreland promoted the concept of the "electronic battlefield" in Vietnam. He envisioned a day when "enemy forces [would] be located, tracked and targeted almost instantaneously through the use of data-links,

computer-assisted intelligence evaluation and automated fire control."[130] Technological superiority did not solve Westmoreland's problems in Southeast Asia. The United States lost in Vietnam and won in Desert Storm because the situations and the strategies were different—not because an RMA occurred in the intervening years. Subsequent American misadventures in Iraq would underscore this fact.

Belief in an RMA can be more than misleading. It can be downright disastrous. America's military ventures in the 1990s concluded with an air war over Kosovo without a single friendly combat fatality.[131] Meanwhile, al-Qaeda sought ways to merge audacity, low-tech weaponry, and internet connectivity to confound a militarily superior United States.[132] In 2001, Washington responded to the attacks of 9/11 with military intervention in Afghanistan. Special operations forces backed up by precision ISR and airstrikes (including armed UAS) enabled the Northern Alliance to rout al-Qaeda and the Taliban, seemingly validating the transformational nature of modern technology. As the United States prepared to invade Iraq in 2003, Defense Secretary Donald Rumsfeld fostered the notion that "[w]ith the help of technology . . . a U.S. intervention could be speedy *and* lethal."[133] American confidence in "information superiority" crashed against jagged rocks of poor assumptions and strategic blunders in Iraq, repudiating the purported RMA of the 1990s.[134] Technology enhanced the warfighting capabilities of the US

military, but it did not bestow victory. As Joseph Nye concluded, "Americans were not mistaken to invest in the revolution in military affairs; they were wrong to think it was sufficient."[135]

Despite their novelty, unmanned systems in all their present forms do not constitute an RMA. As Section I recounted, their development began before the Wright Brothers' first flight. They lie upon a continuum, not astride a singularity. As Michael Ignatieff explains, "the battlefield has been emptying for centuries," transitioning from massed troops to dispersed elements as humans have developed weapons with increased range and precision.[136] Debate over the morality of distance warfare predates unmanned systems by hundreds of years: medieval knights derided longbow archers as un-chivalric cowards, and Japan's samurai culture shunned firearms until the 1850s. Unmanned systems' utility in armed conflict remains entirely dependent on the situation and the strategy chosen. The author is not alone in the opinion that unmanned systems are not an RMA. Medea Benjamin, no fan of unmanned systems, instead argues that they represent a "progressive evolution" in surveillance and killing, not a revolutionizing force.[137]

The USAF's greatest achievements with UAS have come through iterative, collaborative approaches and adaptations—not via technological wizardry. This is not a new story. By the end of World War I, military airplanes already were flying every type of mission that they do today, with the exception of nuclear bombing. In the interwar period, premier airpower advocates such as Giulio Douhet and William "Billy" Mitchell were themselves aviators. These days, the most strident voices on unmanned systems hail from academia or industry.[138] P.W. Singer is one of the leading authorities on unmanned systems, but he tips his hand when he uses catchy terms like

"killer application" to describe them.[139] Robotic independence would constitute a significant leap, perhaps akin to the advent of nuclear weapons (the only plausible RMA to date, in this author's opinion), but the US military is not moving inexorably toward this fate.

There is no "Red Button of Death"

One of the most prevalent misconceptions distorting the discourse on unmanned systems is the illusion of an instantaneous kill-chain: a "red button" of death that allows national leaders to kill capriciously.[140] Micah Zenko, another respected authority on unmanned systems, claims that they provide "a near-instantaneous 'find-fix-finish' loop."[141] He contrasts this responsiveness with the time required to plan and execute the 1998 cruise missile strikes that targeted Osama bin Laden. The problem with this argument is that it compares the prompt fly-out of a Hellfire to the extended flight of a Tomahawk cruise missile, without acknowledging the unseen mountains of deductive effort behind the decision to launch either. The FMV recording from a Predator that one might glimpse on *WikiLeaks* is but a fraction of the intelligence collection, analysis, and exploitation that goes into operations involving unmanned systems.[142]

To some degree, the US military has been its own worst enemy in this regard. Top commanders with access to FMV have tended to become overly involved in tactical operations.[143] Micromanagement undermines the mutual trust that is vital to the military chain of command. It also leads to unnecessary delays, as commanders overloaded with information endeavor to make all of the decisions, rather than letting their subordinates exercise the initiative inherent in mission

4706 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

command.[144] This problem is not new. In May 1975, President Gerald Ford himself intervened in an ongoing operation to recover the crew of the *Mayaguez*, a US ship hijacked by the Khmer Rouge. He and his advisors repeatedly questioned tactical decisions and prohibited Navy planes from disabling a hostage-laden enemy ship at sea, resulting in a disastrous island assault during which forty US Marines died.[145] Real-time intelligence from unmanned systems only increases a commander's temptation to meddle, but instant responsiveness, in most cases, is an illusion.

The exception to the myth of the "instant kill" further strengthens the case for decentralized execution with regard to unmanned systems. RPAs providing direct support to friendly ground units can enable rapid decisions regarding lethal force within the constraints of strict ROE.[146] In Iraq and Afghanistan, a common insurgent tactic has been to emplace mortar tubes or IEDs and then activate them remotely, while the combatants disappear into the civilian landscape. When empowered by their commanders, UAS crews can detect, confirm, and engage these hostile targets more effectively than calling in a manned airstrike or artillery barrage.[147] This responsiveness exists only because multiple individuals have done their homework. The process of identifying patterns of life, tracking enemy movements, identifying likely ambush spots, detecting hostile activity, confirming target coordinates, avoiding noncombatants, and then guiding weapons all the way to impact, is a team effort. Moreover, the team is legally (and morally) responsible if something ever goes wrong.[148]

Total Situational Awareness is an Illusion

The myth of instant responsiveness couples with the notion that unmanned systems finally offer a path to "battlespace awareness," which is another term for *total* SA. The US military's experiences in Iraq and Afghanistan should have taught its commanders and strategists that these phrases represent metaphors, not tangible goals. Nevertheless, the belief persists that technology can clear away the fog of war, despite decades of contradictory evidence.[149]

During the Kosovo conflict, state-of-the-art NATO aircraft expended tons of ordnance on dummy tanks and other decoys that appeared real from fifteen thousand feet.[150] Modern UAS might have been better at discerning fact from fiction, but this simply would have prompted the Serbs to devise alternate countermeasures (increased use of human shields, perhaps). Moreover, Serbian air defenses would have taken a significant toll on exposed UAS. In the decade preceding the 2003 Iraq War, the USAF flew numerous U-2 missions over Iraq that transmitted plentiful SIGINT and imagery to analysts, but decision-makers still lacked accurate information regarding Saddam Hussein's weapons programs.[151] Furthermore, technical data could not answer the subjective questions about Iraqi society that led to insurgency there once the regime collapsed. If the United States had possessed a fleet of UAS at the time, they would have collected more information than U-2s and orbiting satellites provided. Would it have made a difference? Perhaps, but information and intelligence are two different things.

The data links that have proven so vital to operations in Iraq and Afghanistan also tend to convince commanders that their SA is higher than it actually is. Modern US ground forces deploy

with "blue force trackers" to communicate friendly positions and movements. These reports aid in command and control, but they say nothing about enemy intentions. Blue force trackers, Link 16, and other networks can transmit detected enemy activity, but no amount of collected data equates to a true "red force tracker."[152] Irregular adversaries also tend to emit fewer of the SIGINT transmissions that advanced ISR technology can detect and exploit.

Persistent, real-time FMV and SIGINT from UAS mitigate some of these intelligence holes, but they also increase "fog" in two ways: they limit contextual awareness while simultaneously overloading data collection resources. A common analogy equates monitoring an FMV feed to looking through a "soda straw": focused clarity of a small space with zero peripheral vision. One study equated remote operation to driving at night, as contextual information normally available to a daytime driver (i.e. a manned system) is missing.[153] If individual Predator feeds actually represented the sum of intelligence on their targets, then such discomfort would be appropriate. Fortunately, this almost never is the case.

UAS cameras and sensors continue to improve from the grainy black-and-white footage of a decade ago, but even high-definition pictures can be enigmatic without proper context. Many pundits argue that a truck full of fruit looks the same as a truck full of weapons.[154] This would be true if the observer viewed the truck in isolation—unaware of its origin, destination, or additional contributing factors. Persistent UAS can address these gaps in SA, if crews receive the time and corroboration needed for accurate characterization. This attention to detail helps explain why only one incident of fratricide has occurred in over a decade of armed UAS operations. On 6 April 2011, a Predator strike killed a Marine and a Navy specialist during a firefight in which the

ground commander mistook them for the enemy.[155] One fratricide still is too many. Compared to historical friendly fire rates, however, this is a remarkable record.

In the quest to build persistent SA across a dynamic battlefield, military forces most often demand improved technology and ever more unmanned systems. What they really need is an improved concept of operations. UAS units in support of American campaigns have had to juggle competing demands from multiple parties. Because its data can go to any facility that has approved access and connectivity, one UAV may simultaneously be supporting several teams of analysts.[156] This system works when all are examining the same target, but it creates conflict when disparate parties each want a single aircraft to observe different things.[157] One proposed technological solution to the "soda straw" conundrum was a multiple-camera pod for the MQ-9 Reaper called Gorgon Stare. Despite a "do not field" recommendation from RPA test pilots who found it impractical, several Gorgon Stare pods made it to operational units. Subsequently, in the spring of 2013, the USAF cut funding for the program.[158]

Failed enterprises like Gorgon Stare indicate that the problem is not the capability to collect FMV and SIGINT, but rather the ability to process and interpret all of the information. Under current procedures, while RPA crews conduct real-time missions, distributed analysts require hours or even days to review reams of data.[159] DARPA and other agencies continue to pursue automated collection and processing capabilities, hoping to use technology to distill

needles of clarity from haystacks of data.[160] Their initiatives obscure the true problem: human interpretation is required to convert information into actionable intelligence. More UAS are not the answer to information overload, especially not swarms of miniature robots that many writers portend.[161] The solution is the development of a strategy that utilizes focused, persistent ISR—not a quest for omnipresent battlespace awareness. Joint planners and operators must know how to ask the right questions, prioritize limited assets, and adapt to changing and unexpected circumstances. Section V addresses this integrated approach.

Proliferation is not Exponential

The exponential growth of unmanned systems in recent years leads many to claim that future development will follow a similar trend. P.W. Singer invokes Moore's Law (which postulates that semiconductor technology doubles roughly biennially) across a broad spectrum of military-related technology including microchips, data storage, wireless networks, and internet bandwidth. He associates this process with the progressive emptying of battlefields due to increasingly precise and lethal modern weapons, but military developments do not follow his logic.[162] Battlefields may be emptying, but unmanned systems have neither alleviated the need for deployed forces nor eliminated the deadly risks of combat. For example, note the number of American ground troops in Kosovo in 1999 (zero) versus the number that invaded Iraq in 2003 (150,000).[163] Destructive potential is not ever increasing, either: the Soviet Union tested the world's most powerful nuclear bomb in 1961, but nuclear weapon yields and arsenals since have

4711 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

shrunk drastically. Context matters—warfare does not follow mathematical projections. Nevertheless, the DOD's statistics on UAS growth are startling indeed.

The increase in the number of hours flown by UAS followed an exponential curve until 2011. Between 1995 and May 2007, UAS crews logged approximately 250,000 hours. They flew another 250,000 hours in the subsequent eighteen months, between May 2007 and November 2008.[164] In 2009 alone, UAS logged nearly 500,000 hours, and by mid-2010, they had surpassed 1,000,000 total flight hours.[165] Between 2001 and 2008, ISR flight time rose by 1,431 percent.[166] In 2004, the USAF could maintain five simultaneous 24-hour Predator combat air patrols (CAPs).[167] In 2009, the Secretary of Defense gave the USAF the objective of supporting fifty Predator and Reaper CAPs, and by July of that year, the USAF had thirty-four CAPs in operation.[168] Washington subsequently raised the target to sixty-five CAPs by mid-2014. The USAF was up to sixty-one simultaneous CAPs by 2013, just four short of the ultimate goal.[169]

In order to accomplish this unprecedented growth, the USAF had to strain its rated pilot force. The USAF's cadre of approximately fifty RPA pilots in the late 1990s had to multiply in response to worldwide commitments post-9/11, and shortages were inevitable.[170] By mid-2007, the USAF had begun to extend the length of pilots' assignments in RPA squadrons. It augmented their ranks with a round of involuntary transfers, forcing many young pilots to transition from

4712 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

manned aircraft to unmanned squadrons before their previous tours were up. Then it further extended assignments, lengthened mobilization periods for Air National Guard and Air Force Reserve RPA pilots, curtailed RPA flight testing, and delayed the opening of the new RPA Weapons School squadron to fulfill operational demands.[171] In 2010, the USAF initiated RPA-only pilot training for officers without prior flying experience, speeding up the pipeline and reducing training costs.[172] As of 2013, the USAF had approximately 1,300 RPA-qualified pilots (8.5 percent of total USAF pilots), projected to increase to 1,650 pilots by 2017.[173]

Something interesting has happened in the last three years: the numbers have leveled off. Since 2010, the US military's UAS flight hours have begun to normalize at roughly 500,000 to 600,000 a year—still an astounding number, but no longer a runaway statistic.[174] USAF pilot shortfalls likewise are stabilizing. Over the past three years, UAS have been busy in the Middle East, Asia, and Africa, but the US military also has departed from Iraq. Future UAS operations in Afghanistan will depend on the ultimate security agreement between the American-led coalition and the Afghan government, but America's footprint there will certainly diminish. According to one analyst, "drawdown is all but inevitable; the USAF simply does not need to maintain 65 combat air patrols unless there are major ground combat operations underway."[175]

4713 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Hence the answer to every security problem is not always "more unmanned systems." When alarmists lament that growth to date "undoubtedly means . . . more countries with drones flying over them, more drone bases, more crashes, more mistakes," they are begging the question.[176] Continued escalation is not a certainty; there is no perpetual motion machine inexorably replicating "drones." The future growth—or retrenchment—of unmanned systems depends on a host of factors, chiefly policymakers' decisions concerning the use of force and the composition of the military. As discussed in Section I, DOD-wide belt-tightening already is revising future UAS plans. Sections IV and V examine policy dynamics in detail.

Are Unmanned Systems Really "More Bang for the Buck?"

In times of constrained budgets, unmanned systems appeal to governments and militaries because they seem cheaper than manned alternatives. The DOD has acknowledged this belief in writing—its *Unmanned Systems Integrated Roadmap FY2011-2036* states: "affordability [will] be treated . . . like a Key Performance Parameter (KPP) such as speed, power, or data rate."[177] Predators and Reapers certainly are cheaper than F-22 Raptors and F-35 Joint Strike Fighters. However, as with the issue of escalation, past performance is not a guarantee of future returns. The cost equation of unmanned systems is more complex than it seems.

The US military rushed the development and deployment of many unmanned systems to satisfy urgent requests from commanders in the field. This nontraditional approach concealed many of these systems' expenses and shortcomings. Funding for many unmanned systems came from wartime contingency appropriations, as opposed to the traditional budget process.[178] Initially, commercial off-the-shelf technology like the Predator or the Talon UGV provided rapid

4714 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

solutions at remarkably low cost. However, as operations continued and the need grew for these systems to integrate with other combat capabilities, problems surfaced. As the *Unmanned Systems Integrated Roadmap* explains, "each unmanned system was procured as a vertically integrated, vendor-proprietary solution . . . this resulted in an inhibition to innovation; increased vulnerability to threats . . . increased complexity . . . [and] increased costs."[179] The DOD is revising the acquisition process for unmanned systems to match traditional practices, and demanding interoperability and open architecture in future designs.[180]

UAS may be cheaper than manned fighters and bombers, but many still cost tens of millions of dollars each, particularly when the cost of ground control stations and communications equipment is included.[181] In 2012 dollars, a Reaper system of four aircraft, ground control station, and satellite uplink costs $30.9 million. A Gray Eagle platoon of four aircraft and all support equipment costs $153.1 million, and a single Global Hawk costs $222.7 million.[182] "They are not expendable, they are very expensive," states General Mike Hostage, commander of Air Combat Command.[183] The Congressional Budget Office agrees: "Although a pilot may not be on board, the advanced sensors carried by unmanned aircraft systems are very expensive and cannot be viewed as expendable."[184] Each crash reduces combat capability.

Regrettably, many such crashes have occurred—but raw numbers are misleading. In 2007, the USAF determined that it had lost 50 percent of its Predators.[185] By 2010, thirty-eight

Predators and Reapers had crashed in Iraq and Afghanistan, at a cost of $3.7 to $5 million each. Nine others had crashed stateside. Ostensibly, the USAF's RPAs were crashing themselves out of existence.[186]

Mishap rates have decreased significantly over the past several years. The 2009 accident rate for the Predator was comparable to that of the F-16 fighter at that aircraft's same stage of development, and better than that of single-engine private planes in the United States. Crash rates for aircraft in general tend to be highest during development and initial operations. The US military accepted the risks associated with deploying untested unmanned systems because the capabilities they provided were worth the cost. Mishap rates for manned aircraft have declined markedly over the past fifty years due to improvements in designs and training, and today unmanned systems are aligning with this trend.[187]

Developers identify modularity as a key affordability factor for future unmanned systems, envisioning a "standardized, low-cost, small- to medium-sized, remotely piloted airframe able to carry mission-specific payloads."[188] This concept (aside from the remote pilot) sounds remarkably like the DOD's original vision for the F-35 Joint Strike Fighter. The Pentagon wanted the F-35 to be an affordable aircraft whose three variants would answer the respective needs of the USAF, Navy, and Marines for decades to come. After years of requirements creep, cost overruns, and broken deadlines, the price tag for each F-35 now stands at $135 million.[189]

The F-35's skyrocketing price tag is no surprise to USAF Lieutenant Colonel Lawrence Spinetta, an experienced pilot and former RPA squadron commander. He notes, "[w]ithout

[189]Harrison, 43. This number comes from the 2012 Defense Budget. In the 2013 Budget, the DOD cut the production rate of the F-35 to reduce total program cost. This move further increases per-unit price, as research and development costs are shared across a smaller fleet. Daggett and Towell, 10.

4716 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

exception, every generation of bomber and fighter aircraft since the Wright Flyer has been an order of magnitude more expensive than its predecessor."[190] However, his claim that "[u]nmanned aircraft . . . offer so much capability for so little money that they represent a way out of the service's force structure death spiral" is either prescience—or fallacy.[191] The exorbitant Global Hawk and the Navy's UCAS certainly challenge such an assertion.

General Hostage's assertion that unmanned systems are nonexpendable is not universal. The *Unmanned Systems Integrated Roadmap* envisions a future in which commanders habitually make decisions to expend (i.e. destroy) robotic vehicles in order to accomplish their missions.[192] It notes, "[i]n order to be expendable, which is often the intent of building an unmanned system, the vehicle must be low-cost."[193] The *Roadmap* does not mention an associated requirement: in order to be expendable, commanders must have enough units that sacrificing them does not exhaust available reserves. Cost equals price-per-unit times the total number of systems purchased. Future designs may be expendable, but this does not mean the total bill will be low. The *Roadmap* is correct to regard affordability as important, but when the same document highlights the need to "protect the defense industrial base," one begins to surmise the intended audience.[194] Unmanned systems can be cost effective only if the US military resists the siren song of cheap, quick fixes perpetually emanating from the purveyors of armaments.

More Machines, Fewer Humans: the Wrong Answer

Personnel costs are a significant component of military budgets. If technology could decrease the ratio of crews-to-vehicles, then unmanned systems might reduce this expense

without sacrificing combat effectiveness. The USAF presently uses one pilot and one sensor operator to control each RPA. This two-to-one ratio does not include the scores of additional personnel involved in the support and intelligence exploitation of each aircraft.

In the mid-2000s, the USAF tested a system called Multi-Aircraft Control (MAC), which allowed one ground control station to manage up to four airborne RPAs during benign operations like transit or holding patterns. The *United States Air Force Unmanned Aircraft Systems Flight Plan 2009-2047* set a goal to implement MAC on a wider scale by late 2010, envisioning 56 percent in manpower savings across the RPA fleet.[195] Such developments prompted drone alarmists to forecast omnipotent puppet masters singlehandedly directing squadrons of lethal drones to incinerate clusters of (presumably innocent) people in distant lands.[196] In actuality, such marionette-like manipulation turned out to be more difficult than expected.

At first glance, MAC may appear analogous to air traffic control (ATC), in which each controller can manage multiple airborne aircraft. However, human factors experts call this analogy "fallacious for projecting the safe human-robot ratio because it ignores the Pilot-in-Command role. . . . If a manned air vehicle encounters difficulties, the ATC does not assume control of the aircraft; the Pilot on board remains in charge of each individual aircraft."[197] The interplay between controllers and pilots is what makes ATC function, particularly when the unexpected occurs. The author's personal experience as a flight leader, instructor pilot, and mission commander in the F-15C Eagle, F-22 Raptor, MQ-1 Predator, and MQ-9 Reaper corroborates this finding. In dynamic situations, flying one's own aircraft while simultaneously directing a formation of four or more fighters is extremely demanding. Proficiency requires years

of training and constant practice. It relies on rigorous tactical standards and prudent delegation to the qualified human aviators operating each additional aircraft.

Studies of multitasking have consistently shown that human performance deteriorates when a person attempts to do several things at once (text messaging while driving, for example). Experiments with unmanned systems have demonstrated that simultaneously controlling multiple vehicles engenders significant risks of lost SA, cognitive overload, and incorrect task prioritization.[198] P.W. Singer notes, "[j]ust having a human operator control two rather than one UAV at a time reduces their performance by an average of 50 percent."[199] One experiment with UGVs found that single operators controlling two vehicles detected less than 25 percent of their targets, but *adding* an additional operator to each system improved detections up to 170 percent– in other words, more humans were the answer, not fewer.[200] Technological solutions that simplify inputs or make displays more intuitive may streamline a remote operator's changeover between the controls of multiple vehicles, but ergonomics cannot eradicate the pitfalls of multitasking.[201]

The USAF's MAC trial ended in 2011-2012 because aircrews found it infeasible and unreliable. One veteran RPA pilot lamented the "inability to build SA as you push into the target area" when flying multiple aircraft.[202] Another explained that MAC control did not suffice when there were "two targets to prosecute or two malfunctioning airplanes. That was more than one

pilot could handle."[203] These "targets" include not just lethal strikes, but any dynamic surveillance task, such as following a vehicle through crowded urban streets or tracking individuals in rugged terrain. A human-flown RPA with real-time FMV is the ideal platform for such volatile situations, but they require singular focus to be successful. The fog and friction of ground combat is even greater than that of airborne operations.[204] One Pentagon report determined, "[e]ven if the tactical commander is aware of the location of all his units, the combat is so fluid and fast-paced that it is very difficult to control them."[205] The Navy's plan to synchronize multiple types of unmanned systems from an LCS in hostile waters portends a multitasking nightmare.[206]

Multi-aircraft control may still be useful for scripted flight plans like those of the Global Hawk (although even its pilots frequently have to intervene manually), but for demanding, unpredictable situations, unmanned systems require one crew per vehicle.[207] Even if MAC could reduce personnel requirements during transit, the ratio of aircraft en route versus those on target would depend on the tactical scenario. A squadron would still need a full roster of pilots standing by to assume aircraft control during intense situations.[208] Only one factor might alter the equation. It is the most controversial subject in the debate over unmanned systems: what if technology could eliminate the need for human control altogether?

Robotic Autonomy

If militaries develop and deploy fully autonomous lethal systems, the character of warfare will change in significant but unpredictable ways. As discussed above, fully autonomous systems to date exist only as experimental prototypes.[209] While academia, industry, and certain DOD entities continue to advocate for increased robotic autonomy, uniformed personnel at all levels remain opposed to relinquishing the human decision over the employment of deadly force.

Full autonomy is distinct from automation or semi-autonomy. An autonomous robot consists of several components: "sensors" to obtain information, "processors" to interpret it, and "effectors" to implement its decisions.[210] Autonomous systems are "self-directed toward a goal in that they do not require outside control, but rather are governed by laws and strategies that direct their behavior . . . [even in] unpredictable situations."[211] They must be capable of "complex decision making, including autonomous mission planning, and [have] the ability to self-adapt to the environment."[212] In contrast, an *automatic* system (an aircraft flying on autopilot with a human monitor, for example) "is not able to define the path . . . or to choose the goal."[213] Semi-autonomous systems implement even more automation, but still do not make decisions. "Fire and forget" missiles, radar-guided air defenses, and mines are semi-autonomous systems.[214]

Department of Defense Directive (DODD) 3000.09, *Autonomy in Weapon Systems,* dated 21 November 2012, spells out the US military's current stance on the subject:

---

[213]Department of Defense, *Unmanned Systems Integrated Roadmap FY2011-2036*, 43.

[214]Department of Defense, Directive 3000.09, *Autonomy in Weapon Systems* (Washington, DC: Department of Defense, 21 November 2012), http://www.dtic.mil/whs/directives/corres/pdf/300009p.pdf (accessed 1 March 2014), 14; Krishnan, 45. While a human does not select the specific target for a mine, one does select its (static) location and fusing function. The device only reacts to a direct stimulus—it does not make a "decision" to explode.

4721 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

> Commanders and operators [shall] exercise appropriate levels of human judgment over the use of force . . . in accordance with the law of war, applicable treaties, weapon system safety rules, and applicable rules of engagement (ROE). . . . Human-supervised autonomous weapon systems may be used . . . for local defense to intercept attempted time-critical or saturation attacks. . . . Autonomous weapon systems may be used to apply non-lethal, non-kinetic force such as some forms of electronic attack.[215]

The regulation permits the military to use semi-autonomous lethal weapon systems under human control, as it has for decades. Ancillary studies may make many assertions about the need for autonomy in future designs, but DODD 3000.09 is plain in its restrictions.[216] Speculation aside, "for the foreseeable future, decisions over the use of force . . . will be retained under human control in unmanned systems."[217]

DODD 3000.09 does not present novel concepts; the US military learned its lessons regarding human-supervised autonomy long ago. In 1960, the United States deployed a radar system designed to detect Soviet ICBM launches and trigger a rapid nuclear response sequence. Shortly after activation, the system lit up with warnings of an incoming attack. Its radar had picked up a large object rising above the horizon: the moon. The system worked as programmed—its designers simply had not taught it to distinguish a missile from a celestial object. An astute commander quickly spotted the error and ended the crisis.[218]

Forays into autonomy have not always ended bloodlessly. On 3 July 1988, a US Navy Aegis cruiser in the Arabian Gulf detected an unknown aircraft. The newly installed air defense system aboard the *Vincennes* misidentified a civilian airliner as an Iranian F-14 fighter. Despite situational evidence to the contrary, the crew trusted the computer and shot down the airliner,

killing all 290 passengers and crew.[219] The human-supervised autonomy of the *Vincennes* would have fit the defensive stipulations of DODD 3000.09, but the crew's actions would have violated the requirement always to exercise human judgment and apply ROE. Today, Phalanx ship-defense guns and the equivalent land-based C-RAM (Counter Rocket, Artillery, and Mortar) can operate under human-supervised autonomy, but only under strict, short-range constraints.[220]

The US military has built up a healthy mistrust of autonomous weapon systems. Nevertheless, academics, think tanks, and industry advocates continue to publish studies proclaiming that autonomy is not just desirable, but necessary and inevitable.[221] In 2011, the Office of the USAF Chief Scientist's *Technology Horizons* asserted, "[i]ncreasing levels of flexible autonomy will be needed for a wider range of Air Force functions."[222] A recent study from the Center for a New American Security concluded: "To realize their full game-changing potential, militaries may need to use more contentious concepts of operation including fully autonomous ISR or even combat missions."[223] Armin Krishnan believes that if Western armed forces "wish to retain their current military advantage in the long run they will need to increasingly substitute soldiers with technology, i.e. robots."[224] These statements all use the word "need" to characterize the importance of autonomy, but all come from sources outside the military chain of command.[225]

4723 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Vignettes that advocate for autonomous systems tend to sound contrived. The *Unmanned Systems Integrated Roadmap* presents a hypothetical scenario wherein friendly autonomous systems neutralize a rogue UUV and destroy a futuristic enemy UAV.[226] In both engagements, friendly actions promptly defeat a non-adaptive foe. Other studies further strain credulity. One proposal from 2006 addresses ROE concerns by suggesting that autonomous robots should "shoot to destroy hostile weapons systems, but not suspected combatants," as if aiming a missile at a vehicle rather than the driver inside changes the outcome.[227] Ronald Arkin, a leading advocate for robotic autonomy, envisions autonomous aircraft programmed to hold fire or select a smaller weapon if a hostile target passes near a hospital. He and his colleagues believe future autonomous systems could even wait to determine whether a person "seems ready to attack" before they shoot at him.[228] These appeals for autonomy casually disregard the reality of warfare in myriad ways. Guileful adversaries habitually leverage protected symbols and structures (i.e. hospitals and religious buildings) in far more complex and nefarious ways than simply driving past them. Determining a human's actual intentions remains squarely in the realm of science fiction.

Empirical evidence does not support lofty aspirations for autonomous weapons systems. To assess whether autonomous systems could replace human soldiers, scientists must develop scenarios that replicate the unpredictability of combat against a live, adaptive foe. As *Technology Horizons* explains, "it is the lack of suitable V&V [verification and validation] methods that prevents all but relatively low levels of autonomy from being certified for use."[229] Robotics

experts have determined that "[a]rtificial intelligence required for vehicle autonomy remains a disappointing technology despite exponential improvements in computing cost and density."[230]

Artificial intelligence can exceed human capacity in certain endeavors. For example, the computer *Deep Blue* beat human chess champion Gary Kasparov in 1997. Chess has relatively simple rules that an adroitly programmed machine can use to generate nearly infinite combinations.[231] Computers excel at chess because all possible moves take place within a "well-defined problem space."[232] Chess is a *complicated* game, with vast possible permutations that nevertheless operate in patterned and finite ways. War, on the other hand, is *complex*: it adapts based on diverse interactions and emergent properties that make it impossible to predict with certainty.[233] In war, a wise adversary hardly ever plays by the "rules." Instead, a deft combatant seeks victory through asymmetric and adaptive methods.

Computers falter when problems do not have clear boundaries. For example, it is difficult for a computer to tell the difference between an apple and a tomato without detailed analysis, as nearly all measures of comparison overlap in some regard (size, shape, color, etc.). Most humans can distinguish between an apple and a tomato—or between a Soviet ICBM and the moon—intuitively.[234] Experiments with teams of autonomous vehicles have found that robotic self-coordination quickly becomes "computationally intractable" because every decision spawns an ever-expanding set of possibilities.[235] Swarms of robots that resemble phenomena in nature are

intriguing but impractical in unscripted scenarios.[236] Human intellect is imperfect, but it has evolved the ability to distill coherency from complex uncertainty without requiring a preprogrammed solution. This explains how pilots can wield formations of aircraft in unfamiliar situations where the research indicates that autonomous robots would quickly run out of ideas.

Autonomy at any level of the decision-making process affects the application of lethal force, even if a human ultimately pulls the trigger. Military operations demand trust and shared understanding, from tactical engagements all the way to strategic direction and planning. A program that could evaluate "up to 3,000 friendly COAs [courses of action] per minute" would be counterproductive because commanders and staffs never would learn why certain options did not make the cut.[237] Commanders and staffs develop courses of action and conduct wargames to focus their planning, not to arrive at perfect solutions (which do not exist).

Any autonomous ISR system designed to cull unnecessary data before sending it to human analysts would have to be pristine, as erroneous omissions could be disastrous.[238] Unfortunately, when autonomous systems are assigned tasks such as "making a prediction of enemy activity . . . the data upon which the diagnosis is based are fuzzy and uncertain. Hence a substantial error rate in diagnostic accuracy is anticipated."[239] Skepticism is critical in order to avoid "automation bias—an overreliance in which people treat information from the robot as fact

without seeking additional information."[240] The crew of the *Vincennes* demonstrated automation bias in 1988 with tragic consequences.

Professional military members accept the personal responsibility inherent in the state sanction of lethal operations. Autonomy threatens to fracture this paradigm, which has legal and ethical implications, but advocates for autonomy are not depraved. Instead, they believe the military needs autonomous robots because future conflicts will demand split-second timing that exceeds human capabilities. The *Unmanned Systems Integrated Roadmap* envisions systems that can "adapt and learn . . . fast enough to provide benefits within the adversary's decision loop."[241] Aerial dogfights, cyber-attacks, and nuclear missile launches do demand near-instantaneous responsiveness, but it is irresponsible to invoke a metaphorical feedback loop to justify imbuing robots with decision-making authority.[242] Military operations as a rule require not reflexive action but rather prudent deliberation and an acceptance of responsibility for both intended effects and unintended consequences.[243] The following section will examine these challenges as they pertain to current policies and strategies involving unmanned systems.

IV – ARE UNMANNED SYSTEMS MAKING MORE TERRORISTS?

The preceding sections analyzed the development of unmanned systems into their present forms, and dissected persistent misconceptions regarding their character and promise. Unmanned

4727 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

systems provide remarkable proven—and potential—capabilities, but they are an amalgamated component of war's evolution, not a divergent path. Like any inanimate tool, unmanned systems themselves are neither legal nor illegal; neither moral nor immoral; neither right nor wrong. When wielded by professionals, they operate well within the accepted rules of warfare.[244] Conversely, if used carelessly or with ill intent, unmanned systems have the potential to explode the notion that warfare—though always regrettable—can be a legitimate, noble endeavor. Unmanned systems must not lower the threshold for when to employ force. The consequences of a cavalier attitude toward violence will be severe.

Too Seductive for Policymakers?

Some analysts believe that the apparent risk-free nature of unmanned systems facilitates the decision to resort to force, making violence a first resort rather than a last one.[245] The nature of risk is among the most complex subjects in warfare, particularly as technology has enabled greater distance and detachment between combatants. With regard to tactical risk, unmanned systems do increase the safety and security of their operators as compared to manned equivalents. In terms of their ability to produce mission success, or their potential to transfer danger to other friendly forces or civilians, unmanned systems are not a riskless proposition.[246]

Since the dawn of aviation, many airpower advocates claimed that aircraft could shatter existing paradigms of protracted warfare on land and at sea, providing shortcuts to victory by striking enemy leadership and economies directly. Their predictions always failed: against

Germany, Japan, North Korea, Vietnam, Iraq, and Serbia, US air attacks alone never broke enemy resistance.[247] Instead, they served as critical enablers for comprehensive approaches (with varying levels of success). Even the atomic bombing of Japan did not produce victory singlehandedly: it represented the final act of years of grueling combat on land, at sea, and in the air, including a strangling naval blockade and the entry of the Soviet Union into the Pacific theater. Nevertheless, despite the dearth of evidence, each technological advance in air combat spawned new pundits who insisted airpower finally could make warfare systematically winnable.[248]

Following the Gulf War and an ill-fated troop deployment to Somalia in 1993, the United States and its allies relied almost exclusively on airpower for a number of military operations. Policymakers chose this option because they did not want to risk ground forces, and because they believed aircraft could accomplish the desired missions. The two no-fly zones over Iraq minimized friendly casualties and contained Iraq at a cost of $1 billion per year, but they did not achieve the ultimate goal of eliminating the regime of Saddam Hussein.[249]

Military options that avoided placing personnel in harm's way altogether were even more attractive to policymakers, as demonstrated by the 1998 cruise missile strikes that (unsuccessfully) targeted Osama bin Laden and his associates. In this instance, the United States unleashed deadly force into Afghanistan and Sudan—nations with which it was not at war.[250] Cruise missile attacks alleviated the need for forward bases and involved zero risk of friendly casualties or prisoners-of-war. Unfortunately, they also failed to achieve their objectives. The United States' international prestige slipped, and the legend of bin Laden grew. The persistence

and accuracy of modern unmanned systems may offer a higher probability of effective targeting than standoff weapons like cruise missiles, but precision does not equate to mission success.[251]

Contemporary American military leaders have been more reluctant to employ force than their civilian counterparts have, and the former tend to eschew simple martial solutions to difficult problems.[252] Sometimes the civilian leadership heeds their advice, and sometimes it rejects it. The no-fly zones over Iraq "were generally supported by senior civilian officials and opposed by senior military officials" (the latter viewed them as ineffective).[253] In the run-up to the 2003 invasion of Iraq, senior civilian leaders spurned top generals' recommendations for a larger force to mitigate risk, instead opting for an RMA-inspired invasion plan.[254] Conversely, in July 2013, Chairman of the Joint Chiefs of Staff Martin Dempsey's astute articulation of the risks of American intervention in Syria's civil war succeeded in mollifying hawkish political leaders.[255]

Unmanned systems appeal to casualty-averse politicians because they reduce the risk of friendly losses, but this factor does not make the decision to employ force an easy one. Every time a commander uses state-sanctioned violence to achieve an end, he or she injects a stimulus into a system that will create multiple-order effects, and the payoff had better be worth the potential cost. Nonetheless, once leaders make the decision to employ force, they are obliged to select tools that minimize risk to friendly forces and reduce collateral damage.[256] Unmanned systems—at times—may be the right answer. General Norton Schwartz, former Air Force Chief of Staff, cannot believe any responsible citizen "would prefer for the American military to absorb

casualties just for the purpose of making war less numbing to the political leadership."[257] Unmanned systems may seem particularly seductive for spying because they alleviate prisoner-of-war concerns in the case of a crash, but this precedent already exists. American satellites have been peering into other nations for more than half a century.

The words and phrases policymakers use to describe strategy directly influence the way nations conceive and fight wars. Use of the term "Global War on Terror" to define American military operations against al-Qaeda and its affiliates after 9/11 gave the impression that the nation was at war with an extensive, incorporated adversary. Consequently, the United States mobilized massive worldwide military and intelligence efforts, including the rapid proliferation of unmanned systems, in a conflict whose very title implied limitless commitment. In reality, those responsible for 9/11 numbered in the hundreds, and most other extremists worldwide had little or no connection with them; grievances tend to be local, not global. The notion that the United States had embarked on a so-called "long war" thus became a self-fulfilling prophecy.[258]

The Administration of President Barack Obama retired the Global War on Terror moniker, but it maintained the assertion that America is committed to a long-term conflict against persistent adversaries.[259] Many worry that the increased use of unmanned systems under the current administration "may lower social barriers in society against the deployment of lethal force," leading to an era of eternal conflict.[260] Speculation aside, this concern highlights the danger of seeking violent solutions to complex problems: absent a comprehensive approach to

solving the root causes of strife, lethal attacks tend to spread discontent and transfer risk. This metastasizing effect explains why new "al-Qaeda" offshoots seem to emerge daily.

Unmanned systems are tools that do not apply equally to all strategic, operational, and tactical problems. If, based on rigorous analysis and debate, the United States' government elects to target a legal combatant with lethal force, then the stealth, persistence, and precision of a UAS may be the appropriate solution. Still, experience to date demonstrates that simply eliminating one or a handful of individuals does not ensure victory. The 2011 *National Military Strategy of the United States* explains: "While such operations disrupt in the short-term, they cannot be decisive and do not constitute a viable long-term strategy for combating extremism."[261]

Policymakers must analyze every contingency specifically to determine how to proceed, rather than grouping distinct crises into a unitary, Cold War-like model. Fortunately, the available evidence indicates that this is what they at least endeavor to do. The latest *National Security Strategy of the United States* repeatedly emphasizes that lethal force is only one component of a comprehensive, interdependent approach to securing the safety and interests of the nation.[262] Technology has increased the global interconnectedness of America's allies and its adversaries alike, but leaders must always tailor decisions involving lethal force to fit specific situations.

Legality

Unmanned systems do not permit a nation to deviate from international laws and norms. During declared armed conflicts between states or between a state and a non-state actor, international humanitarian law applies. Under this framework, lethal attacks must be *proportional* (devastation must not outweigh the intended gain) and *discriminating* (they must target lawful

combatants and not civilians, also called *distinction*).[263] Violence must reach a defined minimum level of intensity, and participants must be governmental authorities or organized armed groups.[264] Modern terrorists strain these guidelines by intentionally embedding their activities among civilian populaces, maintaining fluid organizational structures, and frequently switching between violent action and peaceful existence, but their flaunting of legal characterization does not make them immune from attack.

International humanitarian law presumes an individual is a noncombatant until proven otherwise. One can lose this protected status based upon "insignia or conduct."[265] Conduct such as propaganda, recruitment, finance, and logistical support to the enemy do not make an individual a targetable combatant.[266] Activities must indicate a "continuous combat function," meaning a person is a member of an armed group and actively participates by planning, commanding, or executing "operations amounting to direct participation in hostilities."[267] A lethal strike from an unmanned system can exemplify proportionality and distinction, or else it can be murder—as the United Nations (UN) Special Rapporteur explains, "[t]he legal test remains whether there is sufficient evidence."[268]

The United States asserts that it uses unmanned systems in a declared armed conflict that began the week after 9/11. On 18 September 2001, the US Congress passed the Authorization for the Use of Military Force. This act legitimated military action against "nations, organizations, or

persons [that] planned, authorized, committed, or aided the terrorist attacks that occurred on September 11, 2001, or harbored such organizations or persons, in order to prevent any future acts of international terrorism against the United States by such nations, organizations or persons."[269] Concurrently, UN Security Council Resolutions 1368 and 1373 provided international justification for state self-defense against transnational threats like al-Qaeda.[270] The United States has carried out UAS strikes in Afghanistan, Pakistan, Yemen, and Somalia under these sanctions, while those in Iraq and Libya fell under other UN authorizations.[271]

Outside of armed conflict, international human rights law regulates violent action. This body of law is stricter: deadly force may only be a last resort to prevent immediate loss of life.[272] In addition, if an armed conflict diminishes below the aforementioned coherence and intensity, human rights law replaces humanitarian law as the accepted standard.[273] Some believe human rights law should apply during armed conflict as well, but this notion is naïve—deadly force is the defining feature of war, not a fallback option.[274] Due to the restrictive nature of human rights law, armed unmanned systems rarely, if ever, belong outside the realm of armed conflict.

Civilian Casualties

War is deplorable even when it is justified, and the deaths of innocent civilians rank high among its horrors. In the past three centuries, wars have claimed the lives of approximately equal numbers of civilians and soldiers.[275] The deaths of noncombatants are tragic but they are legal as long as belligerents adhere to the laws of armed conflict and do not intentionally target or wilfully harm them.[276] Incidental civilian casualties may technically be permissible, but in an age of instant global connectivity, every innocent death risks derailing a nation's strategy and empowering its adversaries.

Civilians have died because of American UAS strikes.[277] In Afghanistan, The UN notes that unmanned systems have accounted for fewer civilian deaths than manned aircraft.[278] General Schwartz asserts that the ratio of civilians to combatants killed by UAS strikes in the Afghan theater is roughly one to seven, far below historical proportions.[279]

The remote, hostile nature of the regions where many UAS strikes take place obfuscates the debate over civilian casualties. In these areas, interloping militants intentionally embed themselves among civilian populations in defiance of humanitarian law.[280] Civilians live in constant fear of becoming collateral damage from an airstrike. The intruders terrorize the locals, murdering anyone suspected of spying.[281] Civilians seldom speak candidly with outsiders for fear

4735 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

of retribution.[282] Owen Bennett-Jones, a British journalist who has spent extensive time in these treacherous regions, belies common perceptions with his assessment:

> The closer you get to the places where the drones are actually landing, the more support for them there is . . . the reason is that these Taliban commanders and fighters are causing absolute havoc in the tribal areas. They are going around killing people, beheading them. They are cutting people's limbs off, writing graffiti in blood from severed limbs . . . people are terrified of them. And these drones come along and kill them.[283]

Marauding terrorists cause far more devastation than American unmanned systems, but this disproportion does not mitigate the costs of civilian deaths due to UAS strikes. The precision of a UAS makes it a far more discriminating weapons system than artillery or other unguided munitions, and its persistence enables crews to wait for shot opportunities that avoid collateral damage.[284] Nevertheless, mistakes have occurred and likely will occur in the future.

Some observers, including Amnesty International and UN Special Rapporteur Christof Heyns, imply that not all civilian deaths are unintentional. They recount follow-up UAS strikes that appeared to target first responders and medical personnel trying to aid victims of an initial attack. If true, these strikes would constitute war crimes.[285] In the author's experience with missions in Afghanistan, as soon as first responders showed up, the shooting was over. The US military does not practice such illegal and deplorable tactics.

Even if unmanned systems shrink the number of civilian casualties to a pittance, the psychological impact on those living underneath protracted air campaigns is severe. Despite their precision in targeting the wrongdoers that Bennett-Jones mentions above, UAS strikes also are alien and unexpected. Civilians fear that any stranger in their midst may be the target of the next

missile impact.[286] One RPA sensor operator empathized that it must be "horrible" to live under such an omnipresent threat.[287] Defense analyst Eliot Cohen believes this constant menace will demoralize America's enemies, but his argument is ahistorical.[288] Humans tend not to accept a feeling of powerlessness, and the notion that enemy militants will succumb to the psychological pressure is nonsense. If they cannot fight their foes on the battlefield, they will find new—often unexpected—ways of striking back elsewhere.[289] Attempting to subdue populations by deploying swarms of UGS to patrol streets and neighborhoods would engender even worse results.

The psychological impact of civilian casualties resulting from protracted campaigns counteracts the benefits of eliminating lawful enemy combatants. In other words, it is bad strategy. The senior commander's guidance in Afghanistan is unequivocal: "If we kill civilians or damage their property in the course of our operations, we will create more enemies than our operations eliminate."[290] Prolonged campaigns in remote areas generate opportunities for enemy propaganda that enrages millions, even if the facts on the ground contradict false claims that UAS strikes are indiscriminate and wanton.[291] When armed unmanned systems act as a component of a comprehensive strategy (comprising more than purely military means), a surgical strike on a high-value target may be a decisive achievement that contributes directly to strategic aims. The

alternative, which Admiral Blair has called a global game of "Whac-A-Mole" that costs approximately $20 million per terrorist each year, is not a viable approach to national security.[292]

Proliferation and Asymmetric Warfare

The policies governing unmanned systems remain controversial, but these systems' effectiveness in America's twenty-first-century conflicts to date is indisputable. Nonetheless, anyone who assumes that they provide an insurmountable advantage under any circumstances is mistaken. GPS signals, satellite links, and the various nodes that support remote operations all have vulnerabilities.[293] Individuals who participate directly in the employment of these systems—including civilian contractors—are lawful combatants regardless of their physical location.[294] On their own, contemporary UAS and other unmanned systems do not stand a chance against advanced militaries. Iran's questionable claim that it crashed an RQ-170 by hacking its control signal suggests that nations are working to develop non-kinetic options to defeat unmanned systems.[295] Increasing autonomy might allay vulnerabilities in communication links, but the costs of erroneous decisions and unintended consequences from autonomous vehicles operating in uncertain situations would far outweigh any gains.

Adversaries have found low-tech ways to confound or exploit vulnerabilities in unmanned systems. Militants in Iraq and Afghanistan used commercial software to intercept Predator video feeds, providing them with counterintelligence and early warning, before coalition forces discovered the breach and encrypted the signals. Pentagon officials knew this vulnerability existed but assumed adversaries would not know how to exploit it, and they did not want to spend

[292]Admiral Blair reached this figure by dividing the annual US intelligence budget of $80 billion by an estimated 4,000 al-Qaeda members worldwide. Benjamin, 209.

4738 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

time and money to upgrade the systems.[296] In an al-Qaeda safe house in Timbuktu, Mali, investigators found a document detailing ways to counter or confuse unmanned systems. Much of its advice was farfetched but certain tactics were remarkably prudent.[297] Taliban fighters supposedly foiled some UGVs simply by tipping them over.[298] Future systems likewise will be susceptible to asymmetric methods: a simple mosquito net would be a significant impediment for a swarm of insect-sized microbots. Nature also gets a vote. Severe weather can keep an entire fleet of UAS grounded regardless of operational needs.[299] Military personnel learn always to have a backup plan, and unmanned systems do not alter this wisdom.

The United States has been the most prolific user of unmanned systems in combat to date, and some critics wish the nation could rewind the clock and reverse what they perceive as an inexorable slide toward robotic war.[300] The belief that the spread of unmanned systems is America's fault, or that the nation singlehandedly could prevent their proliferation, is specious. At last count, eighty-seven countries have unmanned systems, and more than forty are developing robotic weapons.[301] Cultures perceive concepts like autonomy in different ways: P.W. Singer finds that some Asian nations have little antipathy toward autonomous weapons.[302] Much of the technology underpinning unmanned systems is inexpensive and available on the commercial

market.[303] Nevertheless, advanced unmanned systems are not simple to develop and field. Micah Zenko notes that many countries have missed multiple deadlines in their unmanned projects.[304]

Precedents do have consequences, and the ways in which the United States uses its unmanned systems influence developments worldwide. The UN has emphasized that there is nothing illegal or immoral about unmanned systems per se—used properly, they are more discriminating and proportional than many other weapons.[305] To set the example, and to retain the authority to condemn others' transgressions, the United States must employ unmanned systems within internationally recognized laws and norms of armed conflict.[306] Collaborative consensus, not gadgetry or expedience, must be the catalyst for any changes to existing frameworks.[307] As Central Intelligence Agency Director John Brennan says, "[i]f we want other nations to use these technologies responsibly, we must use them responsibly."[308] Countries will continue to develop some weapons in secret, as they always have, but international sales demand transparency and regulation.[309] These measures will enable the United States and its allies to use unmanned systems effectively while retaining the license to dissuade violations by less scrupulous actors.[310]

International frameworks do not change the fact that asymmetry is a fundamental component of warfare: no military wants a "fair fight."[311] Combatants always work to maximize

their advantages while confounding those of their enemies.[312] Technology can provide a temporary edge but overconfidence is perilous, for opponents always devise ways to counterbalance one-sided advantages.[313] America must not assume that its enemies' answer to unmanned systems will be corresponding machines of their own. For example, terrorists to date have not been particularly interested in unmanned systems as weapons of choice.[314] Likewise, the notion that superior unmanned systems are the only way to defeat hostile unmanned vehicles is myopic. The US military must employ tactics, technologies, and strategies that can adapt to evolving and unexpected situations.[315] The final section of this project will discuss three ways the United States can enhance the utility of unmanned systems as instruments of national security.

V – WHERE TO GO FROM HERE

Unmanned systems do not fundamentally alter the nature or character of warfare. They are tools whose effectiveness depends on the ways a nation chooses to perceive and utilize them. The US military must select, educate, and equip professionals who can wield unmanned systems with the skill and discipline that the profession of arms demands. The Services must fully integrate the tactics and technology of unmanned systems with manned components of the force, as both will be crucial in future endeavors. Leaders should never allow technology to dictate policy or strategy; unmanned systems must always fit into legitimate and comprehensive plans.

4741 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Professionalism

Just as unmanned systems do not alter the nature of warfare, they do not change what it means to serve as a member of the profession of arms. The fact that one is not at mortal risk while controlling an unmanned system does not mean that one will never face danger in the course of a career. Thousands of service members who originally performed support roles have deployed to Iraq and Afghanistan since 9/11, and many have experienced battle firsthand. Like other forward-positioned personnel, deployed RPA operators routinely endure mortar and rocket attacks within yards of their duty stations.[316] In the author's experience, RPA pilots and sensor operators are every bit as committed to military service as fighter pilots or infantrymen. In today's military, some "will close with the enemy while others will not. Regardless of the nature of the weapons system, the end result is still the same."[317] Volunteers for military service must understand that this vocation entails participation in organized violence, regardless of one's current job description. One who is "never prepared to take a life" should not enlist in the first place.[318]

All of the Services identify a "warrior ethos" as essential to military service, but what they actually demand is a "professional military ethos."[319] Americans want a military culture that espouses not belligerence but rather traits like "sacrifice, courage, bravery, aggressiveness and discipline."[320] Critics claim that unmanned systems eliminate the need for valor.[321] Colonel Eric Matthewson, a highly experienced USAF RPA pilot, retorts that valor need not always involve physical danger: "Valor is doing what is right. Valor is about your motivations and the ends that

---

you seek. It is doing what is right for the right reasons."[322] Unmanned systems operators who understand that they are integral to national security—and who receive recognition for their deeds—will be poised to exercise the restraint and judgment that their profession requires.[323]

The profession of arms also entails accountability for one's actions, and unmanned systems do not change this fact. The legal and ethical implications of killing do not vary based on one's proximity to the violence.[324] In February 2010, misleading communication from a Predator crew led to an airstrike that killed twenty-three Afghan civilians. An investigation of the incident led to disciplinary sanctions for the USAF RPA operators and several US Army officers who were also involved in the event.[325] Section III explained why robotic autonomy is infeasible from a pragmatic standpoint. The legal and ethical demands of military service further condemn the concept of robot warfare: if no human were accountable for lethal force, then the links between intent, action, and consequence that characterize state-sanctioned violence would be broken.[326]

Military service members understand that their profession involves killing, but this knowledge does not eliminate the traumatic nature of violence, even violence experienced remotely. A December 2011 study of six hundred USAF RPA pilots found 42 percent reporting "moderate to high operational stress," with 20 percent reporting "burnout."[327] Instances of posttraumatic stress disorder (PTSD) among unmanned systems operators are unfortunate but unsurprising. The intimate view provided by unmanned systems gives their operators a visceral

link with the enemy that a fighter pilot, sailor, or artillery crewmember may never experience.[328] The author can attest that the seconds between pulling the trigger and a Hellfire missile's impact seem to last an eternity, even when the target is definitely hostile. The sounds and sights of distant comrades under fire provoke equally gut-wrenching emotions.[329] PTSD is a predictable reaction to the horror of war. Unmanned systems do not remove it—nor should they. The US military has a sworn duty to care for traumatized service members, but it must not imagine that it can eliminate the fundamental causes of PTSD. Anyone who believes technology can make war painless has no business in its commission.

To maintain the professionalism and readiness that leads to success in war, units that operate unmanned systems require capable leadership, vibrant esprit, and robust training—not gadgetry. It is past time to retire the insulting label of "cubicle warriors" that totally misrepresents the way forces employ unmanned systems today.[330] America needs talented, experienced, prudent individuals in control of its military unmanned systems. The Services must cultivate and appoint commanders who can focus their units on mission success without neglecting the strains of remote combat on personnel and their families. Amid the challenges of nonstop operations, units must nourish the camaraderie and shared identity that sustain all successful military forces.

As troops redeploy from Afghanistan, the operating tempo should slacken for many units that operate unmanned systems.[331] Units must utilize this leeway to implement continuous training programs that emphasize the tactical proficiency and practical expertise needed in unfamiliar situations. These programs also groom future instructors and leaders.[332] In 2009, the

USAF Weapons School, which develops elite tacticians for all major USAF weapons systems, inaugurated a squadron for RPA pilots.[333] The other Services would benefit from similar programs. Simulator-based training is useful, but it does not replace hands-on instruction and mentorship.[334] The skills needed to wield unmanned systems may differ from those that are ideal for manned platforms, but the obligation to train and promote talented individuals is the same.[335]

The current environment supports the normalization of assignments and careers involving unmanned systems. America's massive military endeavors following 9/11 obliged the DOD to generate combat power in various caustic ways. Involuntary assignments to unmanned systems ostensibly represented punishment tours and career-enders.[336] This era is concluding. As unmanned systems gain legitimacy, assignment to them no longer equates to a hardship tour. Enlisted Army UAS operators currently promote at higher-than-average rates.[337] Conversely, promotion and command opportunities for USAF RPA pilots lag behind those of other career tracks. Besides involuntary assignments, constant surge operations prevented many of these individuals from attending professional military education or other career broadening opportunities, leading to a lower promotion rate for RPA pilots as compared to their peers.[338] This inequity must improve commensurate to the emerging balance between manned and unmanned

platforms.[339] The Services should cultivate service members with distinct aptitude for remote operations, but they also must develop individuals with broader experience.[340] Leaders with expertise in both manned and unmanned operations will be vital to future force development and integration.

Unmanned systems designed for pure troop support in benign skies do not require rated pilots, but platforms capable of participating in complex air campaigns will continue to demand officer aviators with the requisite qualifications and authority.[341] UAS operations since 2001 have occurred under an umbrella of friendly air supremacy. This condition masks the challenges of joint operations in the event an adversary does not cede total control of the airspace and frequency spectrum. Contested air operations will remain the domain of specialized, rated aviators for the foreseeable future.

Integrated Technology and Tactics

In order to prevail in future conflicts, the US military must fully integrate the technology and tactics of unmanned systems with the other components of national defense. This is not an "either-or" dilemma: manned and unmanned systems both have important roles to play. The nation's wartime experiences since 1991 have furthered a misleading sense of American dominance in conventional military operations, prompting some to presume this lead is so

---

4746 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

insurmountable that advanced weapons are simply boondoggles.[342] This assumption is myopic. America cannot assume air supremacy in future wars, nor can it expect unfettered access to the electromagnetic spectrum, and both are critical elements for unmanned operations.[343] Modern air defenses would annihilate most existing UAS platforms that entered their engagement zones without additional support.[344] Kinetic weapons are not the only threats: future adversaries will use electronic warfare and cyber-attacks to blunt US military endeavors.[345] Simple malfunctions and unintentional radio jamming by friendly forces already have spoiled many UAS missions.[346]

Technology can help address these challenges without resorting to autonomous killing robots. The USAF's use of Link 16 and laser weapon guidance to integrate RPAs with manned platforms is archetypal. Against advanced foes, technological solutions that enable seamless integration among disparate platforms ensure adaptability and resilience.[347] Compression and encryption techniques can reduce the ever-increasing strain on frequency bandwidth.[348] The US military should equip unmanned systems with defensive countermeasures and a wider array of weapons, including air-to-air capable UAS. Unmanned systems may still falter against advanced defenses and severe electronic jamming, but this does not mean they are irrelevant in these

[347]Department of Defense, *Unmanned Systems Integrated Roadmap FY2011-2036*, 3, 30-31; US Air Force Chief Scientist, *Technology Horizons*, 43. Unmanned systems are not the only platforms that have struggled with integration. The F-22's original designers assumed the advanced Raptor would not want to risk electronic detection in order to collaborate with other platforms, so they did not include the ability to transmit via Link 16. The author spent two years testing multimillion-dollar workarounds to provide this critical (and still unfinished) capability.

[348]Department of Defense, *Unmanned Systems Integrated Roadmap FY2011-2036*, 28, 67-68.

4747 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

arenas.[349] Remote vehicles that lose communications can be configured to loiter or transit through contested zones, rather than automatically returning to base, until friendly forces regain the airwaves.[350] Unmanned systems must be able to communicate via multiple links.[351] In order to prevail against a fully integrated US military, an enemy would need to defeat every component simultaneously, not just block a single network or frequency band.

Technology is effective only when optimally employed. The US military has made great strides integrating unmanned systems under combat conditions. It must build upon these successes with rigorous joint training. As historical precedents reveal, innovative thinking, comprehensive evaluation, and constant practice are more important than technology alone. In the 1930s, traditionalists in Britain and America resisted the integration of tanks into their armies, while Germany developed the combined tactics that became blitzkrieg.[352] The Allies learned to integrate mechanized ground forces, bombers, and fighters only after bloody experiences on the battlefields of Europe and the Pacific.[353] In order to set the conditions for optimal integration of manned and unmanned systems, the nation must maintain robust military training facilities. It also must open national airspace to UAS flights that adhere to strict safety regulations.[354] The Services must practice realistic scenarios that replicate advanced adversaries, and they always must train to fight as a joint team—just as they have on the battlefield for more than a decade.[355]

4748 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

The final piece of the integration puzzle is the establishment of adaptable joint doctrine to govern the command and control of unmanned systems. America must prepare for multiple contingencies with varying levels of intensity and simultaneity. UGS, UMS, and small UAS will remain under the direct control of their respective ground units or ships, but larger, highly capable unmanned systems need more flexibility to shift rapidly between missions. Army UAS operators deploy with ground forces to preserve continuity and esprit, but this setup is far less effective than the USAF's satellite-enabled remote split operations (RSO). One study found that, assuming a baseline of 132 UAVs, USAF RSO could maintain thirty-four 24-hour CAPs while the Army's model could sustain only twelve.[356] The Army should consider adopting the RSO model, and trust its capable troops to build camaraderie and unity of effort despite the distance.[357]

UAS that fly above five hundred feet need to be included in the Joint Force Air Component Commander's (JFACC's) purview.[358] In exchange for this overarching authority, the JFACC and his AOC must be willing to delegate varying levels of tactical control to forward-deployed echelons commensurate with a given situation. Accordingly, the Services have begun to utilize the Air Component Coordination Element, a forward-positioned air liaison that represents the JFACC, to address prior frustrations regarding over-centralization of air assets.[359] An intense air campaign versus a robust adversary will require different command and control than

4749 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

counterinsurgency operations.[360] Joint doctrine must evolve to address both effectively. Mutual trust among the Services is the linchpin.

Manned and unmanned aircraft recently demonstrated the value of integration. In March 2013, a flight of Iranian F-4 Phantoms attempted to intercept an MQ-1 Predator in the Arabian Gulf. The Iranian pilots quickly changed their minds when an F-22 Raptor suddenly appeared in their formation and radioed them that they "really ought to go home."[361] Unmanned systems may be on the rise, but advanced manned weapons systems remain vital for deterrence and domain superiority.

Prudent Policy and Comprehensive Strategy

If policies that include unmanned systems are defective, professional human control and effective force integration will not be enough to produce favorable results. The US government must never compromise its reputation as a law-abiding, responsible global actor for the sake of expedience or opportunity.[362] Policies driven by fear lead to dark places—they lead to waterboarding, Abu Ghraib, and errant UAS strikes. Diligent analysis and multinational collaboration are the real catalysts of US national security. It is time to dismiss all notions of a global conflict against monolithic terrorism and properly articulate ongoing American efforts for what they truly are: discrete operations against specific adversaries.[363] In order to reinforce

America's commitments to justice and human rights worldwide, Washington should make good on its promises to increase transparency and accountability regarding unmanned systems.[364]

Unmanned systems exist within conceivable approaches to warfare—they are not iconoclastic. They are tools to support strategy, which Colin Gray defines as "the bridge that relates military power to political purpose."[365] Knowledge of tactical options is important for the strategist, but a comprehensive approach to national challenges never depends upon a single tactic or technology.[366] For instance, nuclear weapons may have underpinned the Cold War strategy of containment, but they were just one of many amalgamated approaches to oppose communism.

While strategy is a never-ending quest for enduring relative advantage, actual military operations must have achievable end states and not endure perpetually. Like airpower to date, unmanned systems alone will not be decisive in warfare.[367] Furthermore, they do not appear to deter prospective enemies.[368] Unmanned systems do not make prolonged, continuous armed conflict desirable; warfare is too complex and adversaries are too adaptable. Neither do unmanned systems offer an instantaneous riposte to unexpected threats. At the strategic level, prudent analysis trumps reflexive reaction every time.

Good strategy advantageously influences the mind and will of both opponents and allies. The ultimate purpose of armed unmanned systems, like other weapons, is to kill people and break things. They are not tools to build nations or prevent state collapse. At best, a lethal UAS strike

can create maneuvering space for comprehensive efforts to achieve strategic goals—at worst, an errant or ill-timed attack could ruin years of collaboration.[369] Likewise, nonlethal ISR from unmanned systems can inform and influence prudent decisions, or else it can deceive its users while enraging others by invading their privacy. US strategy must meld precision targeting with "*psychological* precision . . . shaping a military operation so as to attain the desired attitudes, beliefs, and perceptions on the part of both the enemy and other observers."[370]

A final vignette from recent operations in Afghanistan offers a microcosm of the way in which unmanned systems can support strategic objectives. In 2008, UAS participated in combined US-Canadian operations in the Kandahar region. Precision strikes from UAS

> represented the culminating point of a rigorous, multidisciplined (intelligence, operations, information operations) process and cumulative understanding of our environment that evolved throughout the deployment. They reduced risk to friendly forces, minimized collateral damage and dislocated the enemy, reducing his freedom of action while marginalizing his strength in the eyes of the population—the key terrain.[371]

The tactical advantages that persistent, precise unmanned systems supplied to joint, multinational forces directly contributed to long-term strategic goals of destabilizing insurgents and securing friendly populations.[372] Disciplined professionals worked tirelessly to integrate unmanned systems into a well-conceived and carefully orchestrated plan. Afghanistan remains a nation in peril, but this example reveals the right way to use unmanned systems within a broader strategy.

Conclusion

Unmanned systems have become instrumental to the national security of the United States. They will continue to evolve as innovators across the planet develop novel ways to

[372]Ibid., 44, 46, 49.

4752 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

employ them. Unmanned systems are here to stay—the issue remains how best to use them. Autonomous killing robots, despite marginal showings to date, are possible. Human ingenuity, especially when stimulated by the contest of warfare, makes many things possible. However, just because something is possible does not mean it is desirable. History is replete with ideas that seemed foolproof in concept but resulted in catastrophe when attempted. Autonomy is a mistake.

Technological improvements should make future unmanned systems easier to operate and incorporate with other military assets. The skillsets required to wield them will evolve. Nevertheless, technology will never replace human perception and judgment in warfare. War is a chimera that transforms before one's eyes. Successful militaries cultivate professional soldiers and leaders with the prudence to comprehend uncertainty and adapt accordingly. Optimal strategy clearly defines its approach and ultimate goals before choosing its means, and it continuously adjusts to suit the environment and the adversary. Wise policy upholds legitimacy and discretion in order to engender support from likeminded allies and marginalize malefactors. Unmanned systems, properly regarded and employed, are integral to all of these concepts.

In 1999, when the author was a cadet at the United States Air Force Academy, then-Brigadier General Mark D. Welsh (now General Welsh, USAF Chief of Staff) gave his first address as Cadet Wing Commandant. He concluded with these words: "War is a horrible, horrible, horrible thing. There is nothing good about it. But it is sometimes necessary. And so somebody better be good at it."[373] No technology—manned or unmanned—will ever alter this timeless wisdom.

Form Approved
OMB No. 0704-0188

Public reporting burden for the collection of information is estimated to average 1 hour per response, including the time for reviewing instructions, searching existing data sources, gathering and maintaining the data needed, and completing and reviewing the collection of information. Send comments regarding this burden estimate or any other aspect of this collection of information, including suggestions for reducing this burden, to Washington Headquarters Services, Directorate for Information Operations and Reports, 1215 Jefferson Davis Highway, Suite 1204, Arlington VA 22202-4302. Respondents should be aware that notwithstanding any other provision of law, no person shall be subject to a penalty for failing to comply with a collection of information if it does not display a currently valid OMB control number.

4768 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Mission and Description

The MQ-1C Gray Eagle Unmanned Aircraft System (MQ-1C Gray Eagle) provides the Division Commander a dedicated, assured, multi-mission Unmanned Aircraft System for the tactical fight assigned to the Combat Aviation Brigade in each Division and supports the Division Fires, Battlefield Surveillance Brigades, and Brigade Combat Teams based upon the Division Commander's priorities. The MQ-1C Gray Eagle will also be assigned to Army Special Operations Forces and the Aerial Exploitation Battalions. MQ-1C Gray Eagle provides reconnaissance, surveillance, and target Acquisition; command and control; communications relay; signals intelligence; electronic warfare; attack; detection of weapons of mass destruction; battle damage assessment; and manned-unmanned teaming capabilities.

The unit of measure for a MQ-1C Gray Eagle is balanced platoons, each with four aircraft and associated support equipment and payloads to include: Electro-Optical/Infrared/Laser Range Finder/Laser Designator, communications relay, and up to four Hellfire Missiles. The Common Sensor Payload and STARlite Synthetic Aperture Radar Ground Moving Target Indicator are one per aircraft. Ground equipment per Platoon includes: two Universal Ground Control Stations, three Universal Ground Data Terminals, one Satellite Communication Ground Data Terminal, one Mobile Ground Control Station per Company, an Automated Take Off and Landing System which includes two Tactical Automatic Landing Systems and ground support equipment to include Ground-Based Sense and Avoid.

4769 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Executive Summary

The MQ-1C Gray Eagle program continues with development, integration, testing, training, production and deployment while supporting the warfighter with two MQ-1C Gray Eagle Quick Reaction Units (four aircraft each and associated support equipment) and a full-up MQ-1C Gray Eagle Company (12 aircraft and 128 Soldiers) deployed in support of combat operations in Afghanistan.

MQ-1C Gray Eagle Initial Operational Test and Evaluation completed in August 2012. Developmental testing in 4th Quarter FY 2013 and 1st Quarter FY 2014 focused on incorporating the Universal Ground Control Station (UGCS) and Universal Ground Data Terminal (UGDT). Testing consisted of transportability and mobility, electromagnetic environmental effects, and software development. Environmental and Developmental Tests are planned for the 2nd and 3rd Quarter FY 2014. Formal Software Qualification Testing will be performed in 4th Quarter FY 2014 to prove out software functionality. These tests will assure technical maturity for a Follow-on Test and Evaluation (FOT&E) planned for June 2015.

On February 5, 2013, the Chief of Staff of the Army approved an Executive Order (EXORD) changing the MQ-1C Gray Eagle fielding configuration to provide greater capability across the Army. The EXORD directs fielding of MQ-1C Gray Eagle companies to ten Army Divisions, one to the National Training Center (NTC), two Army Special Operations Forces (ARSOF) units, and two to the Aerial Exploitation Battalions (AEB) for a total of 15 companies. The two ARSOF companies will be configured with 12 aircraft each (24 total) and the 13 units assigned to Army Divisions, NTC and the AEB's will be fielded with nine aircraft each (117 total) while Continental United States (CONUS) based. Seven aircraft are assigned to the institutional training base at Fort Huachuca, Arizona. The four remaining aircraft are for attrition. When a company or AEB assigned to a division deploys Outside the Continental United States (OCONUS), the Army will reassign equipment, as required, to bring the company to full Gray Eagle System equipment strength (12 aircraft and associated ground support equipment). All EXORD requirements will be met without exceeding the procurement objective of 152 aircraft and ground support equipment and Program of Record funding.

Each company will be integrated with the following payloads: Electro-Optical/Infrared, Laser Range Finder/Laser Designator, Synthetic Aperture Radar/Ground Moving Target Indicator, communications relay, and four HELLFIRE missiles. Ground support equipment for a 12 aircraft company includes six UGCS, seven UGDT, three Satellite Communication Ground Data Terminals, one Mobile Ground Control Station, and the Automated Take Off and Landing System consisting of six Tactical Automatic Landing System-Tracking Subsystem and ground support equipment.

The Full Rate Production (FRP) Defense Acquisition Board (DAB) completed June 14, 2013 and an Acquisition Decision Memorandum (ADM) approved procurement of up to 49 unmanned aircraft and associated ground support equipment which brings the total program quantity to 152 aircraft. The approved quantity satisfies 100-percent of the total procurement objective for the MQ-1C Gray Eagle program. The ADM changed the program classification from ACAT ID to ACAT IC.

An updated APB based on the DAB approved cost estimate was approved on September 12, 2013. Although the fielding strategy has evolved with the Chief of Staff EXORD, the Army will continue to use the 31 platoon metric to determine program APUC and PAUC. MQ-1C Gray Eagle has demonstrated meeting six of seven Key Performance Parameters (KPP). For the Net Ready KPP, Link-16 has not fully demonstrated meeting the threshold requirement. The Army approved deferring meeting this capability to FOT&E which is planned for June 2015.

Major contracting actions completed since the 2012 SAR include:

4770 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

- Initial FRP1 contract. FRP1 is a Firm Fixed Price (FFP) contract for 15 aircraft and associated ground equipment.
- FRP1 also includes a priced option for four aircraft and associated ground equipment. The option was exercised December 6, 2013 using FY 2014 funds.
- Award of a Cost Plus Fixed Fee (CPFF)/Cost Plus Incentive Fee contract for Pre-Planned Product Improvement (P3I) which allows for development efforts for FOT&E.
- Award of a CPFF Engineering Services contract (FY 2013 - FY 2017) which allows for integration, inspection, analysis and corrective action, test and evaluation for system hardware, software, and components and support of the MQ-1C Gray Eagle systems allocated among Base Engineering Service Memoranda.
- Modification to the Performance Based Logistics contract for performance from May 2013 to May 2014.

The FY 2014 RDT&E appropriation funds MQ-1C Gray Eagle at the FY 2014 PB request of $10.9M. However, a Congressional reduction of $81.3M from the Aircraft Procurement, Army budget request of $518.5M has resulted in a deferral of the planned production and incorporation of Ka-band (military) satellite communications.

Additionally, the FY 2014 appropriation did not include funding for the four war replacement aircraft in the Overseas Contingency Operations (OCO) request. The change in fielding strategy within the existing 152 programmed aircraft reduced the number of attrition aircraft from 21 to four, making the impact of the OCO reduction more significant.

There are no significant software-related issues with this program at this time.

Confidence Level for Current APB Cost 50% -

The Independent Cost Estimate (ICE) to support the MQ-1C Gray Eagle program Milestone C decision, like all life cycle cost estimates previously performed by the Cost Assessment and Program Evaluation (CAPE) office, is built upon a product-oriented work breakdown structure, based on historical actual cost information to the maximum extent possible, and, most importantly, based on conservative assumptions that are consistent with actual demonstrated contractor and government performance for a series of acquisition programs in which the Department has been successful.

The confidence level for the Full Rate Production-aproved Acquisition Program Baseline (APB) is 50% and is based on the May 9, 2013, approved Army Cost Position and are in accordance with Army cost guidance, Army Regulations (AR) 11-18. It is difficult to calculate mathematically the precise confidence levels associated with life cycle cost estimates prepared for Major Defense Acquisition Programs (MDAPs). Based on the rigor in methods used in building estimates, the strong adherence to the collection and use of historical cost information, and the review of applied assumptions, we project that it is about equally likely that the estimate will prove too low or too high for execution of the program described.

4782 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Quantity	SAR Baseline Prod Est	Current APB Production	Current Estimate
RDT&E	2	2	2
Procurement	29	29	29
Total	31	31	31

The unit of measure for a MQ-1C Gray Eagle is balanced Platoons, each with four aircraft and associated support equipment and payloads to include: Electro-Optical/Infrared/Laser Range Finder/Laser Designator, communications relay, and up to four Hellfire Missiles. The Common Sensor Payload and STARlite Synthetic Aperture Radar Ground Moving Target Indicator are one per aircraft. Ground equipment per Platoon includes: two Universal Ground Control Stations, three Universal Ground Data Terminals, one Satellite Communication Ground Data Terminal, one Mobile Ground Control Station per Company, an Automated Take Off and Landing System which includes two Tactical Automatic Landing Systems and ground support equipment to include Ground-Based Sense and Avoid.

Although the Army’s fielding strategy has evolved, the Army will continue to use the 29 platoon metric to determine APUC and the 31 platoon metric to determine PAUC. A balanced platoon contains four aircraft and ground support equipment and is the historic metric used to determine APUC and PAUC.

Low Rate Initial Production

	Initial LRIP Decision	Current Total LRIP
Approval Date	3/29/2010	7/3/2012
Approved Quantity	2	6
Reference	Milestone C ADM	LRIP III ADM
Start Year	2010	2012
End Year	2011	2015

The Current Total LRIP Quantity is more than 10% of the total production quantity due to Milestone Decision Authority directed the LRIP quantities to facilitate the MQ-1C Gray Eagle capability entrance into theater as quickly as possible.

Initial LRIP Decision
The original LRIP quantity was two MQ-1C Gray Eagle systems which equates to six platoon sets (24 aircraft).

Current Total LRIP
The Current Total LRIP quantity is six MQ-1C Gray Eagle systems which equates to 18 platoon sets and includes LRIP I (24 aircraft and two attrition aircraft), LRIP II (24 aircraft and five attrition aircraft) and LRIP III (29 aircraft).

Adjustment for current and prior escalation. (Estimating)	+3.9	+4.2
Revised estimate that supports changes in Army baseline strategy for stationing and fielding the MQ-1C Gray Eagle. (Estimating)	+126.1	+148.6
MILCON Subtotal	+130.0	+148.6

4800 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Contracts

Appropriation: Acq O&M	
Contract Name	**Gray Eagle PBL**
Contractor	General Atomics - Aeronautical Systems, Inc.
Contractor Location	14200 Kirkham Way Poway, CA 92064
Contract Number, Type	W58RGZ-12-C-0075, CPFF/CPIF
Award Date	May 08, 2012
Definitization Date	September 27, 2012

Initial Contract Price ($M)			Current Contract Price ($M)			Estimated Price at Completion ($M)	
Target	Ceiling	Qty	Target	Ceiling	Qty	Contractor	Program Manager
221.4	N/A	N/A	498.3	N/A	N/A	463.3	437.6

Target Price Change Explanation

The difference between the Initial Contract Price Target and the Current Contract Price Target is due to exercising the FY 2013 option.

Variance	Cost Variance	Schedule Variance
Cumulative Variances To Date (1/31/2014)	+6.3	-7.9
Previous Cumulative Variances	+6.3	-7.6
Net Change	+0.0	-0.3

Cost and Schedule Variance Explanations

The unfavorable net change in the schedule variance is due to Ground Control Equipment Spares that were impacted by technical issues associated with the Ground Data Terminal. An obsolete vendor component drove additional software analysis and impacted assembly.

4801 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Appropriation: Procurement	
Contract Name	**LRIP 3**
Contractor	General Atomics - Aeronautical Systems, Inc.
Contractor Location	14200 Kirkham Way Poway, CA 92064
Contract Number, Type	W58RGZ-12-C-0057, FPIF
Award Date	July 06, 2012
Definitization Date	July 06, 2012

Initial Contract Price ($M)			Current Contract Price ($M)			Estimated Price at Completion ($M)	
Target	Ceiling	Qty	Target	Ceiling	Qty	Contractor	Program Manager
411.0	424.6	29	438.2	452.7	29	436.8	437.0

Target Price Change Explanation

The difference between the Initial Contract Price Target and the Current Contract Price Target is due to contract modifications P00001 through P00011 adding a platoon set of ground equipment and updated spares list.

Variance	Cost Variance	Schedule Variance
Cumulative Variances To Date (1/31/2014)	-1.8	-46.8
Previous Cumulative Variances	-0.9	+1.0
Net Change	-0.9	-47.8

Cost and Schedule Variance Explanations

The unfavorable net change in the cost variance is due to Work In Process on lower level assemblies. Performance on lower level assemblies will be claimed when production reaches Earned Value methodology thresholds.

The unfavorable net change in the schedule variance is due to late receipt of Universal Ground Data Terminal (UGDT), Initial Spares, and Tactical Control Data Link (TCDL). UGDT delayed by late receipt of hardware. Initial Spares delayed by lack of agreement on spares kits list with AAI Corporation and late deliveries from L-3 Communications. TCDL impacted by redesign of two Circuit Card Assemblies. The current schedule variance has no impact to the fielding schedule.

4802 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Appropriation: Procurement	
Contract Name	**LRIP II**
Contractor	General Atomics - Aeronautical Systems, Inc.
Contractor Location	14200 Kirkham Way Poway, CA 92064
Contract Number, Type	W58RGZ-11-C-0099, FPIF
Award Date	April 08, 2011
Definitization Date	December 06, 2011

Initial Contract Price ($M)			Current Contract Price ($M)			Estimated Price at Completion ($M)	
Target	Ceiling	Qty	Target	Ceiling	Qty	Contractor	Program Manager
354.0	N/A	26	310.2	321.8	29	329.0	328.4

Target Price Change Explanation

The difference between the Initial Contract Price Target and the Current Contract Price Target is due to the Initial Contract Price Target being based on a Not To Exceed price.

Variance	Cost Variance	Schedule Variance
Cumulative Variances To Date (1/31/2014)	-7.0	-10.9
Previous Cumulative Variances	-1.8	-6.8
Net Change	-5.2	-4.1

Cost and Schedule Variance Explanations

The unfavorable net change in the cost variance is due to Integration, Assembly, Test and Checkout hours required during Phase 2 and Phase 3 flight line testing; including troubleshooting Government Furnished Equipment radios, incorporation of engineering changes, payloads, and rework tasks to support/correct critical engine related issues, and Ground Support Equipment line items that are in scope but were unplanned in the baseline.

The unfavorable net change in the schedule variance is due to delays for rework on Universal Ground Data Terminal Generation 3 modem Circuit Card Assemblies and delays related to software version 4.3.1.

Contract Comments

This contract is more than 90% complete; therefore, this is the final report for this contract.

Contract quantity 25 of 29 aircraft were delivered.

4803 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

242.5	287.9	26	292.6	317.3	26	289.1	286.3

Target Price Change Explanation

The difference between the Initial Contract Price Target and the Current Contract Price Target is due to contract modifications through P00074.

Variance	Cost Variance	Schedule Variance
Cumulative Variances To Date (1/31/2014)	+10.4	-0.7
Previous Cumulative Variances	+1.4	-1.3
Net Change	+9.0	+0.6

Cost and Schedule Variance Explanations

The favorable net change in the cost variance is due to overestimated support on Program Management and System Engineering.

The favorable net change in the schedule variance is due to completion of Ground Support Equipment, specifically Half Rack and Breakout Boxes that were originally delayed due to engineering changes.

Contract Comments

This contract is more than 90% complete; therefore, this is the final report for this contract.

Contract quantity 25 of 26 were delivered.

The difference between the Initial Contract Price Target and the Current Contract Price Target is due to Contract Modifications through Mod P00099.

Variance	Cost Variance	Schedule Variance
Cumulative Variances To Date (1/31/2014)	+7.8	-1.8
Previous Cumulative Variances	+10.6	-0.9
Net Change	-2.8	-0.9

Cost and Schedule Variance Explanations

The unfavorable net change in the cost variance is due to efforts on a Sub-Engineering Services Memorandum (SESM) needing additional Electromagnetic Interference (EMI) testing and the purchase of new equipment to resolve compatibility issues.

The unfavorable net change in the schedule variance is due to efforts on a SESM needing additional EMI testing, delays in the alternator delivery, and design rework on the High Power Distribution Module.

Contract Comments

This contract is more than 90% complete; therefore, this is the final report for this contract.

4806 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Appropriation: RDT&E

Contract Name	**Production Readiness Test Asset (PRTA)**
Contractor	General Atomics - Aeronautical Systems, Inc.
Contractor Location	14200 Kirkham Way Poway, CA 92064
Contract Number, Type	W58RGZ-09-C-0151, CPIF
Award Date	April 28, 2009
Definitization Date	April 20, 2010

Initial Contract Price ($M)			Current Contract Price ($M)			Estimated Price at Completion ($M)	
Target	Ceiling	Qty	Target	Ceiling	Qty	Contractor	Program Manager
48.0	N/A	N/A	83.6	N/A	N/A	72.6	74.6

Target Price Change Explanation

The difference between the Initial Contract Price Target and the Current Contract Price Target is due to contract definitization at $40.60M with options exercised during Calendar Years 2010 - 2012, and Contract Modifications through P00063.

Variance	Cost Variance	Schedule Variance
Cumulative Variances To Date (1/31/2014)	+12.4	-1.1
Previous Cumulative Variances	+8.0	-2.2
Net Change	+4.4	+1.1

Cost and Schedule Variance Explanations

The favorable net change in the cost variance is due to overestimated support on Datalink Spares, Program Management, and System Engineering.

The favorable net change in the schedule variance is due to completion of Datalink Spares kits originally delayed by late material from subcontractor.

Contract Comments

This contract is more than 90% complete; therefore, this is the final report for this contract.

Contract W58RGZ-09-C-0151, Production Readiness Test Asset was included in the 2012 SAR and is listed in the 2013 SAR as a reference. This contract is not currently in the top six largest contracts. The contract is over 90 percent complete so this is the final report for this contract.

Operating and Support Cost

MQ-1C Gray Eagle

Assumptions and Ground Rules

Cost Estimate Reference:
The O&S Current Estimate is based on the June 14, 2013 Defense Acquisition Board (DAB) approved Full Rate Production (FRP) Army Cost Position (ACP). Operation and Maintenance cost was based on actual Unmanned Aircraft System (UAS) consumption data, analogy to Predator, O&S Management Information System (OSMIS) Blackhawk data. The cost is applied as steady state across the MQ-1C Gray Eagle program in accordance with the program schedule which includes a total approved procurement objective of 152 aircraft.

The unit of measure for a MQ-1C Gray Eagle is balanced Platoons, each with four aircraft and associated support equipment and payloads to include: Electro-Optical/Infrared/Laser Designator, communications relay, and up to four Hellfire Missiles. The Common Sensor Payload and STARlite Synthetic Aperture Radar Ground Moving Target Indicator are one per aircraft. Ground equipment per Platoon includes: two Universal Ground Control Stations, three Universal Ground Data Terminals, one Satellite Communication Ground Data Terminal, one Mobile Ground Control Station per Company, an Automated Take Off and Landing System which includes two Tactical Automatic Landing Systems and ground support equipment to include Ground-Based Sense and Avoid. A MQ-1C Gray Eagle Company is configured into three equal platoons and includes nine MQ-1C Gray Eagle aircraft for conventional companies (non-deployed) and when deployed, the Army will bring the company to full MQ-1C Gray Eagle System strength (12 aircraft and associated ground support equipment).

Sustainment Strategy:
The O&S cost is based on 15 MQ-1C Gray Eagle companies with a 20-year service plus one training base with a 27-year service life.

A Performance Based Logistics (PBL) contract was awarded May 8, 2012. The contract includes one base year plus two, one-year options. Soldiers will operate systems and perform 85% of the basic field maintenance. The Field Service Representative (FSR) will support remaining 15% of basic field maintenance through PBL efforts. Some of the Depot Level Reparables will be accomplished by organic depots through a Public Private Partnership (PPP) arrangement. The PPP with organic depot efforts will be determined through Cost Benefit Analysis and application of Title 10 USC 2426 and 50/50 rule.

Antecedent Information:
There is no antecedent to this program.

4809 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Unitized O&S Costs BY2010 $M		
Cost Element	**MQ-1C Gray Eagle Average annual cost per company**	**No Antecedent (Antecedent) N/A**
Unit-Level Manpower	10.300	0.000
Unit Operations	1.300	0.000
Maintenance	3.460	0.000
Sustaining Support	3.750	0.000
Continuing System Improvements	0.360	0.000
Indirect Support	0.870	0.000
Other	2.460	0.000
Total	22.500	--

Unitized Cost Comments:
O&S unitized cost is based on 15 companies with a 20-year service life plus one training base with a 27-year service life. (15 companies x 20 year service life + one training base x 27 year service life = 327 Operational Systems).

The unitized average annual cost per system (Platoon) is $22.5M (BY$ 2010), ($7357.3M / 327 Operational Systems). The $2.460M Other cost is Operations and Maintenance related, Military Pay and Allowances (Medical & Morale, Welfare, Recreation).

Total O&S Costs Comments:
HISTORICAL NOTES:

1) Prior to the FRP Decision, the average annual cost per MQ-1C Gray Eagle system was $31.84M.

2) Ownership Cost Key System Attribute was not required for post Milestone B documents per the March 10, 2007 Life Cycle Sustainment Outcome Metrics memorandum and the December 1, 2007 Guide to Sustainment Key Performance Parameter memorandum from the Deputy Under Secretary of Defense for Material Readiness and Maintenance Policy. After that time, the program was reclassified as an Acquisition Category ID Major Defense Acquisition Program.

Mission and Description

The MQ-1C Gray Eagle Unmanned Aircraft System (MQ-1C Gray Eagle) provides the Division Commander a dedicated, assured, multi-mission Unmanned Aircraft System for the tactical fight assigned to the Combat Aviation Brigade in each Division and supports the Division Fires, Battlefield Surveillance Brigades, and Brigade Combat Teams based upon the Division Commander's priorities. The MQ-1C Gray Eagle will also be assigned to Army Special Operations Forces and the Aerial Exploitation Battalions. MQ-1C Gray Eagle provides reconnaissance, surveillance, and target Acquisition; command and control; communications relay; signals intelligence; electronic warfare; attack; detection of weapons of mass destruction; battle damage assessment; and manned-unmanned teaming capabilities.

The unit of measure for a MQ-1C Gray Eagle is balanced platoons, each with four aircraft and associated support equipment and payloads to include: Electro-Optical/Infrared/Laser Range Finder/Laser Designator, communications relay, and up to four Hellfire Missiles. The Common Sensor Payload and STARlite Synthetic Aperture Radar Ground Moving Target Indicator are one per aircraft. Ground equipment per Platoon includes: two Universal Ground Control Stations, three Universal Ground Data Terminals, one Satellite Communication Ground Data Terminal, one Mobile Ground Control Station per Company, an Automated Take Off and Landing System which includes two Tactical Automatic Landing Systems and ground support equipment to include Ground-Based Sense and Avoid.

4817 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Executive Summary

The MQ-1C Gray Eagle program continues with development, integration, testing, training, production and deployment while supporting the warfighter with two MQ-1C Gray Eagle Quick Reaction Units (four aircraft each and associated support equipment) and a full-up MQ-1C Gray Eagle Company (12 aircraft and 128 Soldiers) deployed in support of combat operations in Afghanistan.

MQ-1C Gray Eagle Initial Operational Test and Evaluation completed in August 2012. Developmental testing in 4th Quarter FY 2013 and 1st Quarter FY 2014 focused on incorporating the Universal Ground Control Station (UGCS) and Universal Ground Data Terminal (UGDT). Testing consisted of transportability and mobility, electromagnetic environmental effects, and software development. Environmental and Developmental Tests are planned for the 2nd and 3rd Quarter FY 2014. Formal Software Qualification Testing will be performed in 4th Quarter FY 2014 to prove out software functionality. These tests will assure technical maturity for a Follow-on Test and Evaluation (FOT&E) planned for June 2015.

On February 5, 2013, the Chief of Staff of the Army approved an Executive Order (EXORD) changing the MQ-1C Gray Eagle fielding configuration to provide greater capability across the Army. The EXORD directs fielding of MQ-1C Gray Eagle companies to ten Army Divisions, one to the National Training Center (NTC), two Army Special Operations Forces (ARSOF) units, and two to the Aerial Exploitation Battalions (AEB) for a total of 15 companies. The two ARSOF companies will be configured with 12 aircraft each (24 total) and the 13 units assigned to Army Divisions, NTC and the AEB's will be fielded with nine aircraft each (117 total) while Continental United States (CONUS) based. Seven aircraft are assigned to the institutional training base at Fort Huachuca, Arizona. The four remaining aircraft are for attrition. When a company or AEB assigned to a division deploys Outside the Continental United States (OCONUS), the Army will reassign equipment, as required, to bring the company to full Gray Eagle System equipment strength (12 aircraft and associated ground support equipment). All EXORD requirements will be met without exceeding the procurement objective of 152 aircraft and ground support equipment and Program of Record funding.

Each company will be integrated with the following payloads: Electro-Optical/Infrared, Laser Range Finder/Laser Designator, Synthetic Aperture Radar/Ground Moving Target Indicator, communications relay, and four HELLFIRE missiles. Ground support equipment for a 12 aircraft company includes six UGCS, seven UGDT, three Satellite Communication Ground Data Terminals, one Mobile Ground Control Station, and the Automated Take Off and Landing System consisting of six Tactical Automatic Landing System-Tracking Subsystem and ground support equipment.

The Full Rate Production (FRP) Defense Acquisition Board (DAB) completed June 14, 2013 and an Acquisition Decision Memorandum (ADM) approved procurement of up to 49 unmanned aircraft and associated ground support equipment which brings the total program quantity to 152 aircraft. The approved quantity satisfies 100-percent of the total procurement objective for the MQ-1C Gray Eagle program. The ADM changed the program classification from ACAT ID to ACAT IC.

An updated APB based on the DAB approved cost estimate was approved on September 12, 2013. Although the fielding strategy has evolved with the Chief of Staff EXORD, the Army will continue to use the 31 platoon metric to determine program APUC and PAUC. MQ-1C Gray Eagle has demonstrated meeting six of seven Key Performance Parameters (KPP). For the Net Ready KPP, Link-16 has not fully demonstrated meeting the threshold requirement. The Army approved deferring meeting this capability to FOT&E which is planned for June 2015.

Major contracting actions completed since the 2012 SAR include:

4818 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

- Initial FRP1 contract. FRP1 is a Firm Fixed Price (FFP) contract for 15 aircraft and associated ground equipment.
- FRP1 also includes a priced option for four aircraft and associated ground equipment. The option was exercised December 6, 2013 using FY 2014 funds.
- Award of a Cost Plus Fixed Fee (CPFF)/Cost Plus Incentive Fee contract for Pre-Planned Product Improvement (P3I) which allows for development efforts for FOT&E.
- Award of a CPFF Engineering Services contract (FY 2013 - FY 2017) which allows for integration, inspection, analysis and corrective action, test and evaluation for system hardware, software, and components and support of the MQ-1C Gray Eagle systems allocated among Base Engineering Service Memoranda.
- Modification to the Performance Based Logistics contract for performance from May 2013 to May 2014.

The FY 2014 RDT&E appropriation funds MQ-1C Gray Eagle at the FY 2014 PB request of $10.9M. However, a Congressional reduction of $81.3M from the Aircraft Procurement, Army budget request of $518.5M has resulted in a deferral of the planned production and incorporation of Ka-band (military) satellite communications.

Additionally, the FY 2014 appropriation did not include funding for the four war replacement aircraft in the Overseas Contingency Operations (OCO) request. The change in fielding strategy within the existing 152 programmed aircraft reduced the number of attrition aircraft from 21 to four, making the impact of the OCO reduction more significant.

There are no significant software-related issues with this program at this time.

Requirements Source

Capability Production Document (CPD) dated March 24, 2009

Change Explanations

(Ch-1) The KPP description in the February 28, 2012 APB was not verbatim from the 2009 JROC approved CPD. The wording in the current APB (APB Change 2) was updated to reflect the exact verbiage from the 2009 JROC approved CPD.

(Ch-2) Updated current estimate parameter to align with September 12, 2013 APB.

Acronyms and Abbreviations

% - Percent
AGMs - Air-to-Ground Missiles
Ao - Operational Availability
ATO - Approval to Operate
CPD - Capability Production Document
DAA - Designated Approval Authority
DISR - Department of Defense Information Technology Standards Registry
EO/IR/LD - Electro-Optical/Infrared/Laser Designator
GCS-V3 - Ground Control Station Version Three
GIG IT - Global Information Grid Information Technology
IA - Information Assurance
IATO - Interim Approval to Operate
JROC - Joint Requirements Oversight Council
KIP - Key Interface Profile
km - Kilometers
KPP - Key Performance Parameter
lbs - Pounds
NATO - North Atlantic Treaty Organization
NCOW RM - Net Centric Operations Warfare Reference Model
PD - Probability of Detection
PR - Probability of Recognition
SAR/GMTI - Synthetic Aperature Radar/Ground Moving Target Indicator
TV - Technical View
UA - Unmanned Aircraft

Confidence Level for Current APB Cost 50% -

The Independent Cost Estimate (ICE) to support the MQ-1C Gray Eagle program Milestone C decision, like all life cycle cost estimates previously performed by the Cost Assessment and Program Evaluation (CAPE) office, is built upon a product-oriented work breakdown structure, based on historical actual cost information to the maximum extent possible, and, most importantly, based on conservative assumptions that are consistent with actual demonstrated contractor and government performance for a series of acquisition programs in which the Department has been successful.

The confidence level for the Full Rate Production-aproved Acquisition Program Baseline (APB) is 50% and is based on the May 9, 2013, approved Army Cost Position and are in accordance with Army cost guidance, Army Regulations (AR) 11-18. It is difficult to calculate mathematically the precise confidence levels associated with life cycle cost estimates prepared for Major Defense Acquisition Programs (MDAPs). Based on the rigor in methods used in building estimates, the strong adherence to the collection and use of historical cost information, and the review of applied assumptions, we project that it is about equally likely that the estimate will prove too low or too high for execution of the program described.

Quantity	SAR Baseline Prod Est	Current APB Production	Current Estimate
RDT&E	2	2	2
Procurement	29	29	29
Total	31	31	31

The unit of measure for a MQ-1C Gray Eagle is balanced Platoons, each with four aircraft and associated support equipment and payloads to include: Electro-Optical/Infrared/Laser Range Finder/Laser Designator, communications relay, and up to four Hellfire Missiles. The Common Sensor Payload and STARlite Synthetic Aperture Radar Ground Moving Target Indicator are one per aircraft. Ground equipment per Platoon includes: two Universal Ground Control Stations, three Universal Ground Data Terminals, one Satellite Communication Ground Data Terminal, one Mobile Ground Control Station per Company, an Automated Take Off and Landing System which includes two Tactical Automatic Landing Systems and ground support equipment to include Ground-Based Sense and Avoid.

Although the Army’s fielding strategy has evolved, the Army will continue to use the 29 platoon metric to determine APUC and the 31 platoon metric to determine PAUC. A balanced platoon contains four aircraft and ground support equipment and is the historic metric used to determine APUC and PAUC.

Low Rate Initial Production

	Initial LRIP Decision	Current Total LRIP
Approval Date	3/29/2010	7/3/2012
Approved Quantity	2	6
Reference	Milestone C ADM	LRIP III ADM
Start Year	2010	2012
End Year	2011	2015

The Current Total LRIP Quantity is more than 10% of the total production quantity due to Milestone Decision Authority directed the LRIP quantities to facilitate the MQ-1C Gray Eagle capability entrance into theater as quickly as possible.

Initial LRIP Decision
The original LRIP quantity was two MQ-1C Gray Eagle systems which equates to six platoon sets (24 aircraft).

Current Total LRIP
The Current Total LRIP quantity is six MQ-1C Gray Eagle systems which equates to 18 platoon sets and includes LRIP I (24 aircraft and two attrition aircraft), LRIP II (24 aircraft and five attrition aircraft) and LRIP III (29 aircraft).

4848 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Contracts

Appropriation: Acq O&M	
Contract Name	**Gray Eagle PBL**
Contractor	General Atomics - Aeronautical Systems, Inc.
Contractor Location	14200 Kirkham Way Poway, CA 92064
Contract Number, Type	W58RGZ-12-C-0075, CPFF/CPIF
Award Date	May 08, 2012
Definitization Date	September 27, 2012

Initial Contract Price ($M)			Current Contract Price ($M)			Estimated Price at Completion ($M)	
Target	Ceiling	Qty	Target	Ceiling	Qty	Contractor	Program Manager
221.4	N/A	N/A	498.3	N/A	N/A	463.3	437.6

Target Price Change Explanation

The difference between the Initial Contract Price Target and the Current Contract Price Target is due to exercising the FY 2013 option.

Variance	Cost Variance	Schedule Variance
Cumulative Variances To Date (1/31/2014)	+6.3	-7.9
Previous Cumulative Variances	+6.3	-7.6
Net Change	+0.0	-0.3

Cost and Schedule Variance Explanations

The unfavorable net change in the schedule variance is due to Ground Control Equipment Spares that were impacted by technical issues associated with the Ground Data Terminal. An obsolete vendor component drove additional software analysis and impacted assembly.

4849 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Appropriation: Procurement	
Contract Name	**LRIP 3**
Contractor	General Atomics - Aeronautical Systems, Inc.
Contractor Location	14200 Kirkham Way Poway, CA 92064
Contract Number, Type	W58RGZ-12-C-0057, FPIF
Award Date	July 06, 2012
Definitization Date	July 06, 2012

Initial Contract Price ($M)			Current Contract Price ($M)			Estimated Price at Completion ($M)	
Target	Ceiling	Qty	Target	Ceiling	Qty	Contractor	Program Manager
411.0	424.6	29	438.2	452.7	29	436.8	437.0

Target Price Change Explanation

The difference between the Initial Contract Price Target and the Current Contract Price Target is due to contract modifications P00001 through P00011 adding a platoon set of ground equipment and updated spares list.

Variance	Cost Variance	Schedule Variance
Cumulative Variances To Date (1/31/2014)	-1.8	-46.8
Previous Cumulative Variances	-0.9	+1.0
Net Change	-0.9	-47.8

Cost and Schedule Variance Explanations

The unfavorable net change in the cost variance is due to Work In Process on lower level assemblies. Performance on lower level assemblies will be claimed when production reaches Earned Value methodology thresholds.

The unfavorable net change in the schedule variance is due to late receipt of Universal Ground Data Terminal (UGDT), Initial Spares, and Tactical Control Data Link (TCDL). UGDT delayed by late receipt of hardware. Initial Spares delayed by lack of agreement on spares kits list with AAI Corporation and late deliveries from L-3 Communications. TCDL impacted by redesign of two Circuit Card Assemblies. The current schedule variance has no impact to the fielding schedule.

4850 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Appropriation: Procurement	
Contract Name	**LRIP II**
Contractor	General Atomics - Aeronautical Systems, Inc.
Contractor Location	14200 Kirkham Way Poway, CA 92064
Contract Number, Type	W58RGZ-11-C-0099, FPIF
Award Date	April 08, 2011
Definitization Date	December 06, 2011

Initial Contract Price ($M)			Current Contract Price ($M)			Estimated Price at Completion ($M)	
Target	Ceiling	Qty	Target	Ceiling	Qty	Contractor	Program Manager
354.0	N/A	26	310.2	321.8	29	329.0	328.4

Target Price Change Explanation

The difference between the Initial Contract Price Target and the Current Contract Price Target is due to the Initial Contract Price Target being based on a Not To Exceed price.

Variance	Cost Variance	Schedule Variance
Cumulative Variances To Date (1/31/2014)	-7.0	-10.9
Previous Cumulative Variances	-1.8	-6.8
Net Change	-5.2	-4.1

Cost and Schedule Variance Explanations

The unfavorable net change in the cost variance is due to Integration, Assembly, Test and Checkout hours required during Phase 2 and Phase 3 flight line testing; including troubleshooting Government Furnished Equipment radios, incorporation of engineering changes, payloads, and rework tasks to support/correct critical engine related issues, and Ground Support Equipment line items that are in scope but were unplanned in the baseline.

The unfavorable net change in the schedule variance is due to delays for rework on Universal Ground Data Terminal Generation 3 modem Circuit Card Assemblies and delays related to software version 4.3.1.

Contract Comments

This contract is more than 90% complete; therefore, this is the final report for this contract.

Contract quantity 25 of 29 aircraft were delivered.

Award Date	September 30, 2009
Definitization Date	September 30, 2009

Initial Contract Price ($M)			Current Contract Price ($M)			Estimated Price at Completion ($M)	
Target	Ceiling	Qty	Target	Ceiling	Qty	Contractor	Program Manager
77.2	N/A	N/A	160.7	N/A	N/A	152.1	153.0

Target Price Change Explanation

The difference between the Initial Contract Price Target and the Current Contract Price Target is due to Contract Modifications through Mod P00099.

Variance	Cost Variance	Schedule Variance
Cumulative Variances To Date (1/31/2014)	+7.8	-1.8
Previous Cumulative Variances	+10.6	-0.9
Net Change	-2.8	-0.9

Cost and Schedule Variance Explanations

The unfavorable net change in the cost variance is due to efforts on a Sub-Engineering Services Memorandum (SESM) needing additional Electromagnetic Interference (EMI) testing and the purchase of new equipment to resolve compatibility issues.

The unfavorable net change in the schedule variance is due to efforts on a SESM needing additional EMI testing, delays in the alternator delivery, and design rework on the High Power Distribution Module.

Contract Comments

This contract is more than 90% complete; therefore, this is the final report for this contract.

4854 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Appropriation: RDT&E	
Contract Name	**Production Readiness Test Asset (PRTA)**
Contractor	General Atomics - Aeronautical Systems, Inc.
Contractor Location	14200 Kirkham Way Poway, CA 92064
Contract Number, Type	W58RGZ-09-C-0151, CPIF
Award Date	April 28, 2009
Definitization Date	April 20, 2010

Initial Contract Price ($M)			Current Contract Price ($M)			Estimated Price at Completion ($M)	
Target	Ceiling	Qty	Target	Ceiling	Qty	Contractor	Program Manager
48.0	N/A	N/A	83.6	N/A	N/A	72.6	74.6

Target Price Change Explanation

The difference between the Initial Contract Price Target and the Current Contract Price Target is due to contract definitization at $40.60M with options exercised during Calendar Years 2010 - 2012, and Contract Modifications through P00063.

Variance	Cost Variance	Schedule Variance
Cumulative Variances To Date (1/31/2014)	+12.4	-1.1
Previous Cumulative Variances	+8.0	-2.2
Net Change	+4.4	+1.1

Cost and Schedule Variance Explanations

The favorable net change in the cost variance is due to overestimated support on Datalink Spares, Program Management, and System Engineering.

The favorable net change in the schedule variance is due to completion of Datalink Spares kits originally delayed by late material from subcontractor.

Contract Comments

This contract is more than 90% complete; therefore, this is the final report for this contract.

Contract W58RGZ-09-C-0151, Production Readiness Test Asset was included in the 2012 SAR and is listed in the 2013 SAR as a reference. This contract is not currently in the top six largest contracts. The contract is over 90 percent complete so this is the final report for this contract.

Operating and Support Cost

MQ-1C Gray Eagle

Assumptions and Ground Rules

Cost Estimate Reference:
The O&S Current Estimate is based on the June 14, 2013 Defense Acquisition Board (DAB) approved Full Rate Production (FRP) Army Cost Position (ACP). Operation and Maintenance cost was based on actual Unmanned Aircraft System (UAS) consumption data, analogy to Predator, O&S Management Information System (OSMIS) Blackhawk data. The cost is applied as steady state across the MQ-1C Gray Eagle program in accordance with the program schedule which includes a total approved procurement objective of 152 aircraft.

The unit of measure for a MQ-1C Gray Eagle is balanced Platoons, each with four aircraft and associated support equipment and payloads to include: Electro-Optical/Infrared/Laser Designator, communications relay, and up to four Hellfire Missiles. The Common Sensor Payload and STARlite Synthetic Aperture Radar Ground Moving Target Indicator are one per aircraft. Ground equipment per Platoon includes: two Universal Ground Control Stations, three Universal Ground Data Terminals, one Satellite Communication Ground Data Terminal, one Mobile Ground Control Station per Company, an Automated Take Off and Landing System which includes two Tactical Automatic Landing Systems and ground support equipment to include Ground-Based Sense and Avoid. A MQ-1C Gray Eagle Company is configured into three equal platoons and includes nine MQ-1C Gray Eagle aircraft for conventional companies (non-deployed) and when deployed, the Army will bring the company to full MQ-1C Gray Eagle System strength (12 aircraft and associated ground support equipment).

Sustainment Strategy:
The O&S cost is based on 15 MQ-1C Gray Eagle companies with a 20-year service plus one training base with a 27-year service life.

A Performance Based Logistics (PBL) contract was awarded May 8, 2012. The contract includes one base year plus two, one-year options. Soldiers will operate systems and perform 85% of the basic field maintenance. The Field Service Representative (FSR) will support remaining 15% of basic field maintenance through PBL efforts. Some of the Depot Level Reparables will be accomplished by organic depots through a Public Private Partnership (PPP) arrangement. The PPP with organic depot efforts will be determined through Cost Benefit Analysis and application of Title 10 USC 2426 and 50/50 rule.

Antecedent Information:
There is no antecedent to this program.

4857 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Unitized O&S Costs BY2010 $M		
Cost Element	**MQ-1C Gray Eagle Average annual cost per company**	**No Antecedent (Antecedent) N/A**
Unit-Level Manpower	10.300	0.000
Unit Operations	1.300	0.000
Maintenance	3.460	0.000
Sustaining Support	3.750	0.000
Continuing System Improvements	0.360	0.000
Indirect Support	0.870	0.000
Other	2.460	0.000
Total	22.500	--

Unitized Cost Comments:
O&S unitized cost is based on 15 companies with a 20-year service life plus one training base with a 27-year service life. (15 companies x 20 year service life + one training base x 27 year service life = 327 Operational Systems).

The unitized average annual cost per system (Platoon) is $22.5M (BY$ 2010), ($7357.3M / 327 Operational Systems). The $2.460M Other cost is Operations and Maintenance related, Military Pay and Allowances (Medical & Morale, Welfare, Recreation).

Gray Eagle Takes Off With New Capabilities

By Ms Kari Hawkins (Redstone) September 21, 2011

DUGWAY PROVING GROUND, Utah -- For Capt. Travis Blaschke, the mission has shifted.

Deployed three times -- as a Black Hawk helicopter pilot in both Afghanistan and Iraq, and as the commander of the first Quick Reaction Capability 1 team with the Gray Eagle in Iraq -- Blaschke knows how well unmanned aircraft systems augment the Army's manned aircraft on the battlefield.

And now he is putting his battle experience to work as the assistant product manager for Gray Eagle, supporting improvements and added capabilities as this medium-altitude, long-endurance unmanned aircraft speeds toward achieving top performance.

"This is a different mission. One is operational and 100 percent focused on completing the tactical mission," Blaschke said. "I've been in the military eight years and during seven of those years I deployed for 30 months. Now my mission is focused on supporting those who are going to fight the war.

"We are evolving our product to better support the war fighter. Gray Eagle is continuing to be deployed. Reliability continues to get better. The system's development is now closer to 95 percent and will get to 100 percent in the near future."

Blaschke and Gray Eagle were at Dugway Proving Ground the week of Sept. 12 to participate in the Manned Unmanned Systems Integration Capability exercise demonstrating the benefits of manned-unmanned teaming. Those benefits include increased situational awareness for both ground and air crews, better reconnaissance of targets and situations, and improved combat information provided in real time.

During 2009-10, Blaschke commanded a quick reaction capability team in Iraq of 16 Soldiers and 24 civilians that flew 4,000 accident-free flight hours to conduct long-dwell, wide-area reconnaissance, surveillance, target acquisition, communications relay and attack missions.

4860 DISTRIBUTION A. NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

"Since we were the first ones to ever field, train and fly this system in wartime we did really well," he said. "Soldiers did all the flying. The team did an extremely good job in supporting the war fighter."

During the first Gray Eagle deployment, Iraqi residents were going to the polls to vote. Gray Eagle was used to provide "a lot of persistence in viewing polling sites and in watching trucks of ballots moving from polling sites," Blaschke said. "We also supported tactically by providing convoy security. We were able to provide full motion video of locations, vehicles and routes. We were used the vast majority of the time for reconnaissance, and for cordon and search of high volume targets and individuals."

As the unit's commander, Blaschke was involved in planning the Gray Eagle's missions based on requests from the division, brigade and company levels.

"We had the opportunity to state how we would support the mission," he said. "We would develop how we were going to execute in coordination with the unit we were supporting. We would ask: How can we support you the best?'"

Gray Eagle is one of several unmanned aircraft systems that are making a difference on the battlefield.

"The unmanned aircraft system is revolutionizing the way we fight wars today," Tim Owings, deputy project manager for Unmanned Aircraft Systems, said. "Vietnam and Korea were known as helicopter wars. Wars in this decade are unmanned aircraft wars. These systems are adding tremendous value on the battlefield every day and they are saving Soldier lives."

Gray Eagle can fly both line of sight involving distances of 200 to 300 kilometers and beyond the line of sight with the help of satellites that can extend its visual capabilities thousands of kilometers from the ground station. It uses electro-optic and infrared systems for target detection and acquisition.

"The system is capable of day and night vision, and it is capable of providing tremendously high fidelity images," Owings explained. "It has a synthetic aperture radar to find moving targets."

Besides running its own missions, the exercise at Dugway Proving Ground demonstrated Gray Eagle's interoperability with the Apache helicopter. The addition of new sensors under each wing to go with the sensor located underneath its fuselage gives Gray Eagle a triple-effect capability, known as triclops. With the currently fielded Block 2 Apache, which was demonstrated at Dugway, these sensors provide added opportunities to view the battlefield. But with the Block 3 Apache, which will be fielded later this year, teaming with a triclops Gray Eagle means on the battlefield that one sensor can be controlled by a crew member aboard an Apache helicopter, a second can transmit video data to a terminal on the ground and the third can be controlled by the Gray Eagle's ground operator.

"The Apache helicopter flies very low, very fast, and has a frontal view of the target," Owings said. "With Gray Eagle, the Apache can also look down. Putting these two systems together is like putting hunting dogs in front of the hunter."

Or, in another battlefield scenario, different sensors can focus on different targets, allowing, for example, a Gray Eagle to track multiple people and vehicles as they scatter after placing an improvised explosive device.

The new sensors give Gray Eagle a "very unique and very powerful capability," Owings said. "This capability is now being tested and will be in theater later this year. Having three sensors on a single aircraft makes it highly capable. The system also can put a laser beacon on a target and then let its missiles fly to that target, which increases its lethality aspect."

Gray Eagle requires two operators. One is the air vehicle operator who flies the vehicle from a ground station. The other is the payload operator who

4861 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

controls the camera and any payloads -- such as four Hellfire missiles -- carried by Gray Eagle.

"We take 18- and 19-year-olds from high school to flight school, and give them the capability to fly this highly automated system," Owings said.

One Gray Eagle unit is still deployed in Iraq. Another one -- Quick Reaction Capability 2 -- is in Afghanistan. A third unit -- QRC 3 -- is getting ready to deploy out of Fort Hood, Texas. It will be the first full size company to deploy with Gray Eagle.

Gray Eagle's effectiveness continues to increase, with improvements still being made in a system that was only 85 percent ready for deployment when Blaschke led the first quick reaction team into combat.

"We were deployed earlier than the original timeline," he said. "So there were growing pains and learning that needed to occur along with more development of the aircraft and the system.

"We all went into it knowing there would be hiccups along the way, and some additional challenges we would have to go through. But it was more important to give the capability to the war fighter at 85 percent solution than to wait through two more years of development to a 100 percent solution. It was a time when we were transitioning from the surge, and war fighters were asking desperately for more unmanned aircraft vehicles and reconnaissance-type platforms. We had the call to quickly deploy."

Blaschke's work with Gray Eagle in theater further showed him the complimentary roles that unmanned systems and manned systems have on the battlefield.

"There's really no replacement for having two pilots with four eyes and four ears. There's no substitute for Soldiers in the cockpit working in support of Soldiers on the ground," he said. "But unmanned systems can augment the work of pilots. They can provide additional sensor capabilities for better situational awareness and longer endurance times."

While an unmanned aircraft vehicle can remain in the air on a mission for 24-plus hours, a helicopter working that length of time would require three refuels that, in turn, require three rotations of helicopters to continue around-the-clock surveillance of a target or situation.

"In a team of manned and unmanned systems, the manned system can continue surveillance while a helicopter goes to refuel or as the helicopters are changed out," Blaschke said. "The UAV can continue to keep the positive identification throughout the mission, and that is really important in an urban situation where you can easily lose a moving vehicle or people if they are not kept under constant surveillance."

With Gray Eagle, as with all unmanned aircraft systems, there still remains a Soldier in the loop who manages the system and runs safety checks. But once hooked on a target, there is a lot of autonomous control of an unmanned system.

During the MUSIC demonstration at Dugway, Gray Eagle interface with the Apache helicopter showed improvements in a manned-unmanned teaming connection that furthers Gray Eagle's "game changing capability for the United States Army," Owings said. "Persistence in the key to what we're trying to achieve."

Apache pilot Maj. Ryan Atkins of the 21st Air Cavalry Brigade at Fort Hood agreed that manned-unmanned teaming is the future of air combat.

"This is another way to provide better situational awareness for the attack team and the team on the ground," said the Iraq and Afghanistan combat veteran. "Unmanned aircraft provide a different angle, a different view of the

4862 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

threat, and better protection for ground forces."

As a veteran aviator, Blaschke is looking forward to the additional capabilities that will be added to Gray Eagle during his time on the system's development team.

"As the first commander, I was on the receiving end of all the good of this system. We received the property, training, support and sustainment. Now, I am on the giving end," he said.

Preface

Training circular (TC) 3-04.62 standardizes aircrew training programs (ATPs) and flight evaluation procedures. This aircrew training manual (ATM) provides specific guidelines for executing small unmanned aircraft system (SUAS) aircrew training. It is based on training principles outlined in Army Doctrine Publication (ADP) & Army Doctrine and Reference Publications (ADRP) 7-0 (Training Units and Developing Leaders) at the Army Training Network at: https://atn.army.mil/index.aspx under the "Unit Training" tab. This ATM establishes crewmember qualification, refresher, mission, and continuation training and evaluation requirements. This manual applies to all SUAS crewmembers and their commanders in the Active Army, the Army National Guard Bureau (NGB), the United States (U.S) Army National Guard (ARNG), the U.S Army Reserve (USAR), and Department of the Army Civilians (DACs) unless otherwise stated, and any unmanned aircraft system (UAS) crewmembers and their commanders not covered by another ATM.

This manual is not a stand-alone document; all the requirements contained in Army regulations (ARs) 600-105 (Aviation Service of Rated Army Officers), and AR 600-106 (Flying Status for Non-rated Army Aviation Personnel), and TC 3.04.62 (Small Unmanned Aircraft System Aircrew Training Program) must be met.

The operator's manual is the governing authority for operation of the aircraft. If differences exist between the maneuver descriptions in the operators' manual and this manual, then this manual is the governing authority for training and flight evaluation purposes only. Implementation of this manual conforms to AR 95-1 (Flight Regulations) and TC 3-04.11. If a conflict exists between this manual, and TC 3-04.11, the ATP commander determines the method of accomplishment based upon the requirement and the unit's mission as to which manual takes precedence.

This manual in conjunction with ARs will help SUAS commanders at all levels; develop a comprehensive ATP. By using this ATM, commanders ensure that individual crewmembers and crew proficiency commensurate with units' mission and that unmanned aircraft crewmembers (UACs) routinely employ standard techniques and procedures.

UACs will use this manual as a "how to" source for performing crewmember duties. It provides performance standards and evaluation guidelines so that crewmembers know the level of performance expected. Each task provides a description of how the task should be perform to meet the standard. ATP commanders of active Army, National Guard, and Army Reserve units operating the SUAS will use this ATM to develop individual commander's task lists for assigned operators. ATP commanders will assign contractor/DAC operators to assist in developing individual commander's task lists tailored to the current contract position using this ATM, AR 95-20, AR 95-23, and/or local command directives.

Commanding officers and master trainers (MTs) will use this manual, AR 95-23, and AR 95-20 as the primary tools to assist the commander in developing and implementing the ATP.

The proponent of this publication is the Directorate of Training and Doctrine (DOTD), Flight Training Branch (FTB), United States Army Aviation Center of Excellence (USAACE). Submit comments and recommendations utilizing the electronic (XFDL) version of Department of the Army (DA) Form 2028 (Recommended Changes to Publications and Blank Forms) found on the Army Publishing Directorate (APD) website, to: Director, Directorate of Training and Doctrine (DOTD), ATTN: Flight Training Branch (FTB) (ATZQ-TDT-F), Building 4507, Andrews Avenue, Fort Rucker, Alabama (AL) 36362-5263, at email: usarmy.rucker.avncoe.mbx.ATZQ-TDT-F@mail.mil or online at: https://www.us.army.mil/suite/page/655026.

This publication implements portions of standardization agreement (STANAG) 3114 (Edition Eight).

This publication has been reviewed for operations security considerations.

4869 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Chapter 1
Introduction

1-1. The training objective of any combat unit is for the unit to be able to conduct combined arms training (CAT). The SUAS aircrew training program (ATP) focuses on individual and crew training. Once the unit establishes individual and crew training programs, it must integrate them into an effective collective training program. TC 3-04.62 links individual and unit collective tasks. The design and management of an effective training program requires the commander to analyze each of these elements. The mission essential task list (METL) identifies collective training and defines the unit as a member of the combined arms team. To ensure the combat proficiency of Army SUAS operators in the combined arms effort, individual proficiency in tasks required to operate an SUAS is essential.

RESPONSIBILITIES

COMMANDER

1-2. According to ADP 7-0, the commander is the primary training manager and trainer for the unit and is responsible for safety programs, standardization programs, and the ATP. The commander bases training on the unit's wartime mission, maintains standards, and evaluates proficiency. The commander also provides the required resources and develops and executes training plans that result in proficient individuals, leaders, and units. The commander has subordinate leaders (officers and noncommissioned officers) that help him or her plan and prepare SUAS training.

MASTER TRAINER

1-3. The SUAS MT is the commander's technical advisor. The MT helps the commander develop, implement, and manage the ATP. The MT designated to conduct initial qualification training will conduct this training in accordance with (IAW) a TRADOC-approved SUAS exportable training package.

1-4. To perform MT duties, the MT will be current and mission qualified (MQ) in the SUAS in which the MT will be performing his or her duties. The MT will conduct unit qualification (mission level [ML] progression), refresher, transition differences training IAW a TRADOC-approved SUAS exportable differences training package and continuation training only for personnel who have completed an approved SUAS initial qualification course. Upon completion of the TRADOC-approved MT course or Directorate of Evaluation and Standardization equivalency, the first field grade commander with organic SUAS assets has the authority to appoint MTs.

1-5. Those MTs selected to conduct initial qualification training IAW an USAACE-approved program of instruction, and appendix will be designated by the first colonel in the chain of command. Initial qualification training will be managed at brigade level or higher by a designated MT that is a qualified graduate of the MT course, current and MQ. This provision is effective when the unit qualification training program" is approved and implemented by the proponent of this manual.

AIRCRAFT OPERATOR

1-6. These individuals perform duties that are essential to the operation of the SUAS.

Note. Aircraft operators (AOs) will perform duties as aircraft/mission operators.

Chapter 2

Aircrew Training Program

This chapter describes requirements for unit qualification (ML progression), refresher and continuation training. The SUAS ATP standardizes UAC training and evaluations to ensure combat readiness. Crewmember qualification requirements will be IAW AR 95-23 and this ATM.

Note. This ATM uses many terms with which SUAS operators may not be familiar. Understanding of these terms is necessary in the use of this publication; therefore, this chapter explains these terms as appropriate.

OVERVIEW

2-1. Goal and applicability. The goal of the ATP is to produce mission-ready SUAS operators. The ATP outlined in this ATM is mandatory for all crewmembers that perform duties controlling the flight of an SUAS or the operation of its mission equipment, as well as preparation, launch, and recovery tasks essential to operate the SUAS. The ATP includes requirements for tasks (see appendix A), SUAS simulator, ML progression, and the Semi-Annual Proficiency and Readiness Test (S-APART). UAC assigned or attached to another service/United States Special Operations Command (USSOCOM) will meet the training program requirements of that service. DA civilian/contractor UAC will be trained and evaluated as specified in writing by the commander as necessary to meet the requirements of their military support job description.

Note. The unit commander may excuse a UAC scheduled for retirement or separation from active duty from all ATP requirements. The UAC may be excused beginning no earlier than 6 months prior to their scheduled retirement or separation date. However, UACs who are excused are prohibited from performing further UAC flight duties.

2-2. Individual/crew qualification. Operators arrive at the unit with various levels of experience. They are recent graduates of a SUAS qualification course or are proven operators with various SUAS backgrounds. These aircrew members progress from mission preparation IAW paragraphs 2-20 and 2-21 to MQ based on a commander's evaluation/proficiency flight evaluation (PFE) by demonstrating proficiency in tasks required (see appendix) and those tasks selected by the commander based on the unit's METL. If required, prior to designation as MQ, training must be conducted and assessed by the appropriate SUAS MT. This process is explained in detail in this TC. This is a prescriptive process mandated by AR 95-23 and must be strictly followed to ensure standardization across our force.

2-3. Mission qualified. MQ operators are those who have completed ML progression training and demonstrated proficiency to be a member of a battle-rostered crew. MQ operators train as crews to sustain and continually improve task proficiency, proficiency in the conduct of the unit's unique METL requirements, and refine the skills necessary to perform as part of the unit.

2-4. Simulators. Simulation is very useful in the conduct of training. Simulators are excellent resources in training emergency procedures, maneuvers that are infrequently conducted with the unmanned aircraft (UA), and as a rehearsal tool for complex portions of operations. They can also be used to correct negative trends found through analysis of accidents, and to practice those skills in a low risk environment. As the fidelity of our simulators improves, environmental training can be very beneficial to our crews.

4872 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

STANDARDIZATION PROGRAM

2-5. Proficiency versus currency. The fielding of modern aircraft such as the RQ-11B, while exponentially increasing the combat capabilities of SUAS forces, creates diverse operational and training challenges. These increased capabilities require individual and crew proficiencies in very complex mission equipment packages, sometimes compounded by harsh flight environments. An ATP that focuses on operator currency rather than proficiency will no longer satisfy SUAS readiness requirements and will be a detriment to training and safety.

2-6. The objectives of a standardization program are the improvement and sustainment of proficiency and readiness among Soldiers and units throughout the Army. Standardization is accomplished through the universal application of approved practices, procedures, and standards.

2-7. Standardization roles. The commander with SUAS assets is responsible for the unit's standardization program..The commander must include standardization throughout the overall training strategy. The commander's primary standardization staff members include subordinate commanders and unit MTs. Standardization must be implemented in all training tasks. Standardization enables units of any size—crews, multiple-aircraft formations, teams, squads, companies, battalions, or brigades—to readily function together to accomplish the warfighting combined arms mission.

2-8. ATP implementation. This publication is the commander's guide for implementing the ATP.

2-9. Integrating operators into the ATP. Upon signing into the unit, operators designated for duty as SUAS operators are members of the unit's ATP. Within 14 days of signing into the unit, operators must present their training folder, if applicable, to the commander or the commander's designated representative. If the training folder is not available, operators will provide the MT with small unmanned aircraft systems manager (SUASMAN) account information. ML status determination is per the commander’s evaluation.

COMMANDER’S EVALUATION

2-10. Purpose. The purpose of the commander's evaluation is to determine the proficiency and initial ML status of newly assigned operators. This evaluation consists of a records review and a PFE, if required. The commander or MT will complete the evaluation within 45 calendar days after the operator is designated for duty as an SUAS operator.

2-11. Records review. Unit commanders, or their designated representative (MT), will review the operator's training folder. They will compare the individual's qualifications with the tasks required by the assigned duty position. If the appropriate ML status can be determined from the records review, the commander will document the ML status on the individual's DA Form 7122-R (Crew Member Training Record).

2-12. PFE. If the initial ML status cannot be determined by the records review or if the commander desires, the operator will undergo a PFE. The PFE should include tasks from each flight mode in which the operator can expect to perform duties. The results of the PFE will determine the operator's ML status. The commander will document the ML status on the individual's DA Form 7122-R.

2-13. Considerations. If, at the time of initial ML status designation, 6 months has passed since the operator has completed any element of a S-APART (standardization evaluation or SUAS operator's manual examination), the operator must complete that element before designation as, or progression to, MQ. Graduates of an SUAS course who are on their first utilization tour are exempt from this requirement; therefore, commanders may not assign these individuals an initial mission qualified status solely on the basis of a records review.

2-14. Required training. After determining the initial ML status, the commander will direct unit qualification (ML progression training), refresher (if UAC has not flown in 180 days), or continuation (all training and evaluations used for developing proficiency) training for the operator as applicable. Time allotted for completion of the required training will start accruing on the date of the ML status designation. If recommended by the MT, operators may credit the flight tasks satisfactorily completed on the PFE toward completion of their ML status training requirements.

4873 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

MISSION-LEVEL STATUS PROGRESSION

2-15. Definition. MLs are the training status classifications of the individual operator. They identify the training phase in which the operator is participating and measure readiness to perform assigned missions. The MLs provide a logical progression of SUAS training based on task proficiency.

2-16. Progression requirements. Operators will progress in ML status by completing tasks in all areas of the SUAS. Once the operator begins training, he or she will have 90 consecutive days to advance from mission preparation to mission qualified status. Once MQ, the operator will have to perform the minimum requirements to maintain this status.

2-17. Exclusion period. ML status progression will exclude days lost due to—

- Temporary duty (TDY) or deployment to a location where the crewmember is unable to fly.
- For RC crewmembers, this includes TDY for civilian employment purposes where the crewmember is physically unable to participate in unit/facility flying activities. This does not include relocation for permanent change of employment.
- Medical or nonmedical suspension from operations.
- Leave approved by the unit commander.
- Grounding of SUAS.
- Non-availability of SUAS due to maintenance or operational considerations, including movement to deployment/redeployment and aircraft preset/reset; preset/reset requirements only apply if 50 percent of the unit's aircraft are not available.
- Documented flight cancellations due to weather and/or maintenance that have had a significant impact on flight operations, as well as restrictions to flight operations due to no fly times from the host country in which the unit operates.

2-18. If the exclusion period exceeds 45 consecutive days, the operator must restart the ML progression cycle. The operator will have 90 consecutive days from this point to progress to the MQ status level. When an operator has not progressed within the required period, the unit commander will investigate, and based on his or her findings, take action according to appropriate directives.

MISSION PREPARATION

2-19. An operator who has been initially designated mission preparation (MP), based on the commander's evaluation, will begin training on all critical and unit selected tasks IAW the appendix as designated by the unit commander. MP programs help operators verify and develop their ability to perform specific tasks that support the unit's METL. Because the goal is proficiency in mission-related tasks, commanders should tailor their task list to meet specific unit needs. An operator progresses from MP to MQ by demonstrating proficiency in all base (1000) and unit (2000) selected tasks to an MT. An operator has 90 consecutive days to progress from MP to MQ. An operator may progress to the MQ status in less time than prescribed in paragraph 2-16 by demonstrating proficiency to an MT. S-APART requirements do not need to be completed while an operator is designated MP. The only requirements are those designated by the commander with assistance from the MT. All MP operators will only operate the system with an MT present and positioned to gain full access to the controls.

MISSION QUALIFIED

2-20. An operator who has completed MP training is considered mission ready and designated MQ. The operator must perform those tasks designated by the unit commander for the operator's table of organization and equipment or table of distribution and allowance position. Once designated MQ, the operator must complete the S-APART requirements.

4874 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

TRAINING YEAR

2-21. The ATP training year is divided into semiannual training periods. The first training period begins the first day of October and continues for 6 months. The second training period begins the first day of April and continues through the end of the fiscal year.

FAILURE TO MEET AIRCREW TRAINING PROGRAM REQUIREMENTS

2-22. Investigations. When ATP requirements are not met, the commander will conduct an investigation. The commander will complete the investigation within 30 days of notification of the failure. After the investigation, the commander will—

- Take one of the following two actions:
  - Extensions of up to 30 days may be given on a one time basis to complete the requirements. The 30-day extension will start after the commander completes the investigation.
  - Request a waiver of requirements IAW paragraphs 2-23 through 2-26.
- Enter restrictions imposed and waivers/extensions granted on DA Form 7122-R in the individual's training folder.
- Restrict operators from performing duties with the SUAS until ATP requirements are met.
- Restrict operators who fail a hands-on performance test from performing the duty for which he or she was evaluated and failed. The restriction will apply to all SUAS with similar operating and handling characteristics. Restrictions will be entered in the operator's DA Form 7122-R and will remain in effect until successful completion of a re-evaluation.
- When the failure is in the operator's primary SUAS, the commander must—
  - Re-designate the individual to MP.
  - Authorize additional training if necessary.
- When the failure is in the operator's additional or alternate SUAS, the commander must—
  - Re-designate the individual to MP.
  - Authorize additional training if necessary.
  - Re-evaluate, retrain or restrict the UAC from performing duties in that SUAS.

Note. A primary SUAS is the system that the UAC primarily operates for that unit (Raven). An additional SUAS would be another SUAS that the UAC is also trained on that is of the same type (Puma). If the UAC were also trained on a rotary-wing UAS, this would be considered an alternate UAS.

2-23. Unit waivers. Unit waivers for primary SUAS ATP requirements may be granted only by commanders of the following:

- Direct reporting unit.
- Army Command
- Army Service Component Command.
- USSOCOM.
- Commander, United States Army Reserve Command (USAR units).
- Chief, ARNG-AV for the Chief, National Guard Bureau (ARNG units).

2-24. Waiver authorization. Commanders ranked colonel and above and the State Army Aviation Officer, may grant unit waivers and/or extensions to ATP requirements for units under their command or state/territory affected by operational deployments. These commanders may grant unit extensions for up to 180 days from their self-established "start training date" after redeployment.

2-25. Individual waivers. Individual waivers to primary SUAS ATP requirements may be granted by the first field grade commander or above in the individual's chain of command.

4875 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

REMOVAL FROM MISSION QUALIFIED STATUS

2-26. Training deficiency. An operator removed from MQ status for a training deficiency must still meet all MQ ATP requirements. ATP requirements met while in a MP status will be applied to the MQ requirements.

2-27. Other than a training deficiency. An operator has until the end of the training period to complete ATP requirements. If an operator is removed from MQ status for other than a training deficiency before the end of the training period (for example, a permanent change of station departure), his or her ATP requirements no longer apply.

CURRENCY

2-28. Frequency. To be considered current, an SUAS operator must—

- Perform a launch, a recovery, and a 15-minute flight of the SUAS or utilization of a compatible simulator every 30 consecutive days. For ARNG and USAR the requirement is every 60 consecutive days.
- Perform a launch, a recovery, and a 15-minute flight of the SUAS every 150 consecutive days.

2-29. Tracking. Tracking actual flight time for a flying hour requirement is impractical and not required. Individual flight records folders are not required; however, documentation of flight operations (sorties) for the purpose of tracking currency is required. Commanders will establish procedures for maintenance of personal flight logs. A qualified sortie is a launch, a recovery, and 15-minute flight of the SUAS.

2-30. Currency lapse. The SUAS operator whose currency has lapsed must complete a proficiency flight evaluation IAW this ATM. Simulators may not be used to reestablish currency.

2-31. Waivers. Waivers to currency may only be granted by Deputy Chief of Staff, G-3/5/7 (DAMO-AV), 400 Army Pentagon, Washington, DC 20310-0400, IAW AR 95-23.

2-32. Similar unmanned aircraft systems. Currency in one series SUAS will satisfy the requirement for all SUAS within the series or group; separate currency is required for all other SUAS. Series SUAS with similar operating and handling characteristics are listed below:

- Raven-RQ-11A/B, 4-channel, 8-channel, and Digital Data Link.
- Puma.
- Wasp.

Note. Currency is not considered an element of the ATP.

This page intentionally left blank.

Chapter 3

Evaluation

This chapter describes evaluation principles and considerations. It also contains guidelines for conducting academic and hands-on performance testing. Evaluations are a primary means of assessing flight standardization and operator proficiency and are a key part of the Army standardization process. Evaluations will be conducted per AR 95-23 and this ATM.

EVALUATION PRINCIPLES

3-1. The value of any evaluation depends on strict adherence to the fundamental principles described below.

- Selection of MTs. The selection of MTs must not be based only on technical qualifications. Criteria for selecting MTs should include demonstrated performance, objectivity, powers of observation, maturity, judgment, the ability to effectively mitigate risk, and the ability to provide constructive comments.
- Method of evaluation. The method of evaluation must be based on uniform and standard objectives. In addition, the evaluation method must be consistent with the unit's mission and adhere to the appropriate standing operating procedures (SOPs) and regulations.
- Participant understanding. Complete understanding of the purpose of the evaluation, by all concerned, is essential. Moreover, the evaluation must be conducted in a manner that is purpose-oriented.
- Participant cooperation. Cooperation by all participants is necessary to fulfill the evaluation's objectives. The emphasis is on all of the participants, not just the examinee.
- Training needs identification. The evaluation must produce specific findings to identify training needs. General comments do not always provide the direction and guidance essential for improvement. The evaluation must pinpoint both strengths and weaknesses.
- Purpose of evaluation. The evaluation will determine the examinee's ability to perform essential hands-on/academic tasks to prescribed standards. Flight evaluations also will determine the examinee's ability to exercise crew coordination in completing these tasks.

Note. All evaluations of an MT will be conducted by an MT.

SEMI-ANNUAL PROFICIENCY AND READINESS TEST

3-2. Purpose and components. The S-APART measures an operator's proficiency and readiness. It consists of a written examination and a hands-on performance test evaluated by an MT as follows:

- SUAS operator's written examination. This open-book exam is prepared at the local level and consists of 25 objective questions that cover the SUAS operator's manual, local airspace, regulations, SOPs, and other pertinent topics as determined by the commander and MT. The minimum passing score is 70 percent.
- Hands-on performance tests. This component consists of oral and flight position evaluations.
  - Paragraph 3-12 lists of oral subjects for the hands-on performance.
  - The appendix lists the evaluation tasks for the hands-on performance.

3-3. S-APART periods. MQ operators must pass each component of the test during their S-APART periods. The S-APART periods are the two-month period ending on March 30th for the first semiannual training period and the two-month period ending on the last day of the fiscal year. While deployed to

4878 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

designated combat or imminent danger areas, the first field grade commander or above in the individual's chain of command should consider reducing this evaluation requirement to once annually. At the end of the training year, the commander must certify that each operator has completed all S-APART requirements. This action serves to recertify the operator in his or her designated duty position(s). An operator designated MQ at any time within this two-month period must complete all S-APART requirements. Operators receive credit for the operator's written examination and hands-on performance test during mission preparation if they complete the tests within the two-month S-APART period.

3-4. Training deficiencies. Operators participating in MP programs are not subject to the S-APART. Operators removed from MQ status due to a training deficiency are subject to the S-APART.

Note. S-APART failures-Operators who fail to meet the S-APART standards will be processed IAW paragraph 2-22.

NO-NOTICE EVALUATION

3-5. A comprehensive no-notice evaluation program is a valuable tool that allows commanders to monitor training effectiveness at all levels. Each commander must establish a no-notice proficiency evaluation program in the unit SOP. No-notice evaluations may be written, oral, hands-on flight evaluation in a UA/compatible flight simulator, or a combination thereof. Ten percent of these evaluations must be hands-on flight evaluations. This program measures the effectiveness of individual, crew, and collective training. Commanders use the results of no-notice evaluations to ensure unit standardization and readiness and to tailor the unit's individual, crew, and collective training programs. Each operator will receive at least one no-notice evaluation per year.

PROFICIENCY FLIGHT EVALUATION

3-6. Administration. The commander directs and administers the PFE using the guidelines established in paragraph 2-12. This evaluation is conducted to determine—

- The individual's ML status upon assignment to the unit if the readiness level cannot be determined through a records review.
- The individual's proficiency when SUAS currency has lapsed IAW paragraph 2-30.
- The individual's proficiency when questioned by the commander.

3-7. Records. After the evaluation, the MT will debrief the individual and complete DA Form 7122-R.

GRADING CONSIDERATIONS

3-8. Oral evaluation. The examinee must demonstrate a working knowledge and understanding of the subject areas presented. The MT will assess the examinee's knowledge during the oral evaluation.

3-9. Hands-on test. Performance standards are based on an ideal situation. Grading is based on meeting the minimum standards. The MT must consider deviations from the ideal during the evaluation and make appropriate adjustments if other than ideal conditions exist.

CONDUCTING EVALUATIONS

3-10. Purpose, sequence and procedures. Evaluations are conducted to determine the operator's ability to perform appropriate duties. Phase 1 and phase 4 are always required. The MT will determine the amount of time devoted to each phase. When the examinee is a MT, the recommended procedure is for the MT to reverse roles with the examinee. When the MT uses this technique, the examinee must understand how the role-reversal will be conducted and when it will be in effect.

PHASE 1-INTRODUCTION

3-11. In this phase, the MT—

4879 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

- Reviews the examinee's records to verify that the examinee meets all prerequisites for the qualification IAW AR 95-23, appendix D (for example initial PFE, qualification completion, instructor qualification, and/or medical screening).
- Confirms the purpose of the flight evaluation, explains the evaluation procedure, and discusses the evaluation standards and criteria to be used.

Note. If the examinee is an MT, he or she will be evaluated on the ability to apply the learning and teaching process outlined in the Federal Aviation Administration's (FAA) Aviation Instructor's Handbook. The examinee must demonstrate a working knowledge of the conditions, standards, and descriptions of the tasks he or she will be instructing/evaluating. The examinee must also demonstrate the ability to determine when tasks are not performed to standard and how to train to standard.

PHASE 2-ACADEMIC/ORAL EXAMINATION

3-12. The examinee must have a working knowledge and understanding of all applicable topics in the respective subject areas. At a minimum, the MT will select two topics from each appropriate subject area. If the examinee is an MT, he or she will also demonstrate the ability to instruct and evaluate any topic.

- Regulations and publications (ATM, AR 95-23, local SOPs, and regulations). Topics in this subject area are—
  - ATP requirements.
  - SOP requirements.
  - Weather restrictions and procedures.
  - Local airspace usage.
  - Publications required for using the SUAS.
  - Forms and records.
- Operating limitations and restrictions. Topics in this subject area are—
  - Battery limits.
  - Airspeed limits.
  - Environmental restrictions.
  - Other limitations.
- SUAS emergency procedures and malfunction analysis. Topics in this subject area are—
  - Emergency terms and their definitions.
  - Battery malfunctions.
  - Loss of link.
  - Mission equipment.
  - No hub communication.
  - Loss of global positioning system.
- Tactical and mission tasks (TC 3-04.62 and unit SOP). Topics in this subject area are—
  - Mission statement and employment methods.
  - Terrain analysis.
  - Use of FalconView, navigational chart, map, and tactical overlay interpretation.
  - Battlefield environment.
  - Fratricide prevention.
  - Tactical reports.
  - Fire support.
  - Downed UA procedures.
  - Mission equipment.
  - Tactical airspace coordination.

4880 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

- Light amplification by stimulated emission of radiation (LASER) operations.
- LASER performance detractors.
- Night mission operation use of lights.

- Aviation instructor's handbook (FAA-H-8083-9). Topics in this subject area are—
  - The learning process.
  - Effective communication.
  - Teaching methods.
  - Types of evaluations.
  - Planning instructional activity.
  - Flight instructor characteristics and responsibilities.
  - Techniques of flight instruction.
  - Human behavior.
  - Teaching process.
  - The instructor as a critic.
  - Instructional aides.
  - Critiques and evaluations.

PHASE 3-FLIGHT EVALUATION

3-13. If this phase is required, the following procedures apply:

- Briefing. The MT will explain the flight evaluation procedure and brief the examinee on which tasks will be evaluated. When evaluating an MT, the MT must advise the examinee that during role reversal the MT may deliberately perform some tasks outside the standard to check the examinee's diagnostic and corrective action skills. The MT will conduct or have the examinee conduct a crew briefing.
- Before-flight procedures. The MT will evaluate the examinee's use of the appropriate technical manuals (TMs), checklists (CLs), technical bulletins (TBs), and/or the integrated electronic technical manual (IETM) as appropriate.
- Flight tasks. The MT will evaluate those tasks listed in appendix A. An MT must demonstrate the ability to instruct and/or evaluate the appropriate tasks. When used as part of the proficiency flight evaluation, the evaluation may include an orientation of the local area, checkpoints, and other pertinent information.
- After-landing tasks. The MT will evaluate the examinee's use of the appropriate TMs, CLs, TBs, and/or the IETM as appropriate.

PHASE 4-DEBRIEFING

3-14. Upon completing the evaluation, the MT will—

- Discuss the examinee's strengths and weaknesses.
- Offer recommendations for improvement.
- Inform the examinee if he or she passed or failed the evaluation and discuss any tasks not performed to standards.
- Complete the applicable/appropriate forms, and ensure the forms are reviewed and initialed by the examinee.

Note. Inform the examinee of any restrictions, limitations, or revocations that the MT will recommend to the commander following an unsatisfactory evaluation.

4881 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

LOCAL AREA ORIENTATION

3-15. Training area orientation. The commander will ensure that operators are given a tour of and a briefing on the training area and facilities. The tour should include the mission planning procedures (location of maps and other flight planning aids) and the airspace operations office. The briefing also should include the items listed below:

- Obtaining maps and charts.
- Obtaining weather information.
- Obtaining range and restricted-area information.
- Information on frequencies and access phone numbers.
- A review of airspace in the local area.

3-16. Range layout and facilities. The commander will ensure that operators are familiar with range facilities.

3-17. Local area orientation flight. Before progressing to MQ, operators will receive a local area orientation flight. Units may conduct this flight along with other training. The commander will determine which orientation items are required for the flight. Items specific to the local area or those that cannot be adequately covered during the ground portion will be pointed out, demonstrated, or discussed during the flight. The orientation flight should include familiarization with local—

- Boundaries.
- Reporting points.
- Prominent terrain features.
- Restricted areas and no-fly areas.
- Tactical training and range areas.
- Airfields, helipads, and frequently used landing zones.
- Obstacles or hazards to flight.

Note. Army commands, particularly those operating near sensitive borders, should establish additional requirements or restrictions for local area orientations.

4882 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

This page intentionally left blank.

Chapter 4
Unit Task Development

AIRCREW TRAINING MANUAL TASK MODEL DEVELOPMENT

4-1. Commanders are authorized to develop additional tasks for inclusion on the commander's task list (CTL), as needed, to accomplish the unit's mission if the appendix does not adequately cover a maneuver or mission that is required. To develop an additional task, the commander will create the task in the format described in this chapter, assign a 3000-series number to the task, and add it to the CTL along with iteration and mode requirements.

4-2. When an additional task is developed by the unit, the commander must perform a risk analysis for performance of the task, and determine training required for personnel to attain proficiency in the task. The commander will ensure that Soldiers receive the necessary academic and flight training for this new task during RL progression and will determine if there is a requirement for an annual evaluation of the task. Commanders will submit a copy of all 3000-series tasks to Commander, USAACE, Directorate of Training and Doctrine, ATTN: ATZQ-TDT-F (UAS Branch), Building 4507, Andrews Avenue, Fort Rucker, Alabama 36362. The additional task(s) must include the following:

- Task number and title.
- Conditions for task performance.
- Standards for task performance.
- Description of task performance.
- Considerations for task performance (such as environmental and safety).
- Training/evaluation requirements.
- References.

TASK FORMAT

4-3. The following format will be used to develop 3000-series tasks (figure 4-1, page 4-2). Each task element is explained further in the following paragraphs.

Note. The following task is intended for *explanation of formatting style only*; it **does not** constitute doctrinal procedure.

4884 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

TASK 3000

Perform Close Combat Support

WARNING

All warnings associated with the task will follow the task title.

CONDITIONS: Condition statements set parameters or sample parameters. They explain what to provide and what to withhold, and may be modified if necessary. Condition statements describe the circumstances under which the task is taught or measured in the learning environment. The individual task condition statement describes the field circumstances (on-the-job or full spectrum operations) under which the individual critical task is performed as closely as possible. It also lists what materials, personnel, and equipment must be provided for task accomplishment.

STANDARDS: The individual task standard describes the minimum acceptable level of performance in the field to successfully accomplish the task under the prescribed conditions. It notes how well someone should perform the task to be considered competent. For SUAS flight tasks, standards are based on ideal conditions.

DESCRIPTION:

1. Crew actions.
   a. Ensure that the correct designation for the crewmember is used in the description to avoid confusion.
   b. Make sure crew actions (for example AO) by all individuals involved to accomplish this task are captured.
2. Procedures.
   a. Procedures identify the preferred method of accomplishing the task.
   b. Make sure that all individual (for example AO) procedures involved to accomplish this task are captured.

ENVIRONMENTAL CONSIDERATIONS:

1. Task considerations define the different requirements for performing the task under different flight modes or under adverse environmental conditions.
2. They must address the unique requirements of performing the task under those conditions.

TRAINING AND EVALUATION REQUIREMENTS:

1. Training. Training may be conducted while operating the aircraft or simulator.
2. Evaluation. The evaluation will be conducted while operating the aircraft.

REFERENCES: FM 3-04.126, FM 3-04.140, and AR 95-23.

Figure 4-1. Example of task format

4885 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

TASK NUMBER

4-4. Task numbers are uppercase, bolded format. Task numbering begins with 3000 and runs sequentially.

TASK TITLE

4-5. The task title describes the performance required of the Soldier on the job. It is frequently referred to as the task. The task title has one action verb, one object, and may also have a qualifier that describes the required action. Task titles are title case, bolded format. Do not use acronyms in the title. Using standard, well-defined verbs—

- Provides/promotes clarity.
- Allows analysts, task selection boards, trainers, and Soldiers to understand what the task title means.
- Prevents duplication. Using standard verbs makes it simple to group tasks by verbs to avoid duplication.
- Promotes application of sound training principles.

WARNINGS, CAUTIONS, AND NOTES

4-6. Figure 4-2 provides examples of warning, cautions, and notes.

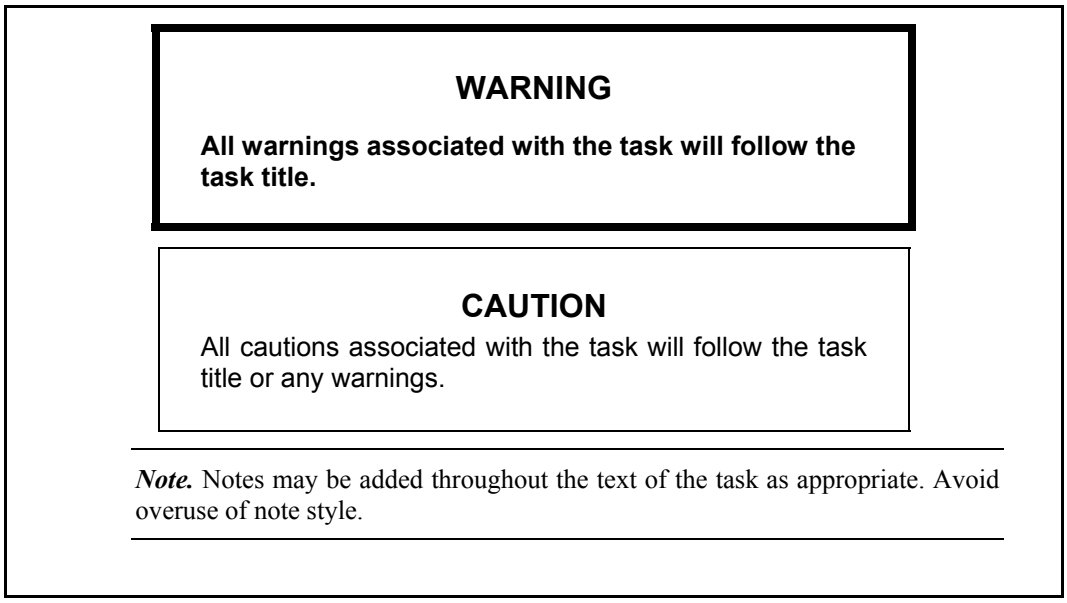

Figure 4-2. Warning, caution, and note examples

CONDITIONS

4-7. Condition statements set parameters or sample parameters. They explain what to provide and what to withhold, and may be modified if necessary. Condition statements describe the circumstances under which the task is taught or measured in the learning environment. The individual task condition statement describes the field circumstances (on-the-job or full spectrum operations) under which the individual critical task is performed as closely as possible. It also lists what materials, personnel, and equipment must be provided for task accomplishment.

4-8. A condition statement has two parts:

- Cue-a word, situation, or other signal for action. An initiating cue is a signal for an individual to begin performing an individual task. An internal cue is a signal to go from one element of a task to another. A terminating cue indicates task completion.

4886 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

- Descriptive data-information that identifies when, why, and where the task is performed and what resources (materials, personnel, and equipment) are required to perform the individual task.

4-9. Write the individual task condition statement in standard paragraph format, containing one or more sentences. Use the following guidelines and tips for writing an individual task condition statement:

- Identify the cue.
  - The cue may be very evident or "understood" when writing a condition statement, and may not require detail.
  - Specifically, identify the cue if it is not evident. Identifying the cue may require studying items, such as, organizational diagrams; mission analysis; threat information; actions performed by outside units, Soldiers, leaders, or events; or procedural manuals.
- Identify/describe the physical setting, or the site of individual task performance. The amount of detail provided varies, based on the effect that the setting has on the task performance.

Note. Not all individual critical tasks are performed on the battlefield or during wartime.

- ***DO NOT*** make the setting too generic or too specific. ***DO NOT*** refer to a training environment. (A task condition is written to field performance, ***NOT*** training performance.
- When the task is performed at multiple performance sites, describe all sites, as practicable.

4-10. Figure 4-3, page 4-5, provides examples of individual task condition statements. Write your individual task condition statements in a similar manner. Each example provides discussion points.

Condition #1 Given a constructed defensive position, entrenching tool, and camouflage nets. Discussion: In this example— • When is-anytime a Soldier or the Soldier's unit is in danger of attack. • Where is-anywhere a Soldier or the Soldier's unit is in danger of attack. • Why is-because there is a threat to the Soldier and/or the Soldier's unit. • Resources required-an entrenching tool and camouflage nets.
Condition #2 You have a casualty who is suffering from a burn. The casualty has no other serious wounds or conditions that were not treated. A canteen and first aid packet are available. Discussion: In this example— • When is-upon finding a burned casualty. • Where is-wherever there is a burned casualty. • Why is-the burn is the most serious injury and controls the boundary of the task. • Resources required-are limited to the resources on hand, which includes a canteen and first aid packet.

Figure 4-3. Individual task condition statements examples

4887 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

4-11. Figure 4-4 provides questions that are useful in determining whether condition statements have been well written.

Does the condition statement address the following issues:

- Describe the conditions under which this task will be performed under operational (field) or selected training conditions?
- Identify the initiating cue?
- Identify the physical setting (when and where the Soldier performs the task)?
- Identify the resources (materials, personnel, and equipment) needed to accomplish the task?
- Utilize job holder language?
- List special conditions when applicable?
- Utilize standard paragraph format?

Figure 4-4. Condition statement issues

SPECIAL CONDITIONS

4-12. A special condition is an aiding or limiting factor that occasionally occurs and affects a Soldier's ability to perform the task to the established standard. These special conditions include, but are not limited to, wearing of mission oriented protective posture level (MOPP) 4, night vision devices, or self-contained breathing apparatus when performing the task (figure 4-5, page 4-6). These unique circumstances are identified as separate special condition statements when conducting the individual task analysis, and are also entered under the conditions tab in the CAC-approved automated development system.

4-13. Writing special condition statements. Once changes to the task performance standard caused by performing the task under a special condition are identified, developers must include them. When writing a special condition statement, be aware that—

- More than one special condition simultaneously may affect task performance.
- A special condition may affect such standards as speed or accuracy.

Condition

You are in an area where chemical agents have been used. You are wearing protective over-garments and mask, or they are immediately available. You encounter a casualty who is breathing and lying on the ground. The casualty is partially dressed in protective clothing and is wearing the protective mask carrier with mask.

Special Condition: MOPP 4.

Figure 4-5. Special condition statement example

STANDARDS

4-14. The individual task standard describes the minimum acceptable level of performance in the field to successfully accomplish the task under the prescribed conditions. It notes how well someone should perform the task to be considered competent. For SUAS flight tasks, standards are based on ideal conditions.

4-15. Standards must be—

- Written in present tense.
- Written in standard paragraph format. The paragraph may contain one or more sentences and may include subparagraphs and/or bullets.
- Written in job holder language.
- Observable, measurable, achievable, objective, valid, reliable, usable, comprehensive, discriminating, and quantifiable.

4-16. A standard statement has two parts:

4888 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

- Performance-A verb phrase that identifies what action the standard will evaluate (that is, the process the Soldier performs, the product produced, or a combination of both).
  - A process standard describes the critical task elements necessary for adequate task performance.
  - A product standard describes the end result of individual task performance. Product standards should be used when the process it takes to perform the task is not important, as long as the product (end result) is correct.
  - A combination standard is used when task performance produces both a product and process.
- Criterion-May include, but is not limited to, accuracy, quantity, speed, and quality. Table 4-1 addresses recommended criteria for each type of task performance.

Table 4-1. Task performance criteria

Individual Task Standard	*Criteria to Use*
Product Standard	Accuracy, tolerances, completeness, format, clarity, number of errors, and quantity.
Process Standard	Sequence, completeness, accuracy, and speed of performance.
Combination Standard	Accuracy, tolerances, completeness, format, clarity, number of errors, quantity, sequence, and speed of performance.

4-17. Parts of example standard statements may include the following:

- Fire all 18 rounds (performance) and hit the target at least 9 times (criterion).
- Camouflage the position (performance), so it cannot be detected from 35 meters forward (criterion).
- Calibrate the altimeter within 1 meter (performance) IAW TM ####-###-#### (criterion).

Note. It is preferred not to use a standard that refers to another document; but, in the case of aircraft maintenance, it is mandatory to use the TM. Duplicating the TM causes extra work and serves no value, since the TM is used when the task is performed.

DESCRIPTION

4-18. Task descriptions are the "how to" portion of the task.

- Descriptions will normally be divided into two sections: crew actions and procedures.
- Ensure that the correct designation for the crewmember is used in the description to avoid confusion.
- Procedures identify the preferred method of accomplishing the task.
- Make sure the standards for the task are clearly defined in the "STANDARDS" section; however, it may be necessary to refer the reader to the description section for specific requirements.
- Deviations from task procedures—but not crew actions—are authorized as long as task standards and safety are not compromised.

CONSIDERATIONS (NOT MANDATORY FOR ALL TASKS)

4-19. Task considerations define the different requirements for performing the task under different flight modes (visual meteorological conditions [VMC], night, or different payload sensors) or under adverse environmental conditions. They must address the unique requirements of performing the task under those conditions.

4889 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

ENVIRONMENTAL CONSIDERATIONS

4-20. The environmental considerations section of a task must address the unique requirements of performing the task under different flight modes or under adverse environmental conditions.

4-21. The following are examples of environmental considerations:

- Altitude, apparent ground speed, and rate of closure are difficult to estimate at night.
- Surrounding terrain or vegetation may decrease contrast and degrade depth perception during the approach. Before descending below obstacles, determine the need for artificial lighting.
- Use proper scanning techniques to avoid spatial disorientation.
- Acquire, identify, track and/or designate targets using the sensor's optimum capabilities (electro-optical, infrared) for a given situation based on mission, enemy, terrain and weather, troops and support available, time available, civil considerations (METT-TC).

REFERENCES

4-22. The reference section of the task lists the sources of information relating to that specific task.

4890 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

This page intentionally left blank.

Chapter 5

Unit Training

Unit commanders are authorized to conduct refresher training at unit level. Operators receiving the training must have attended the initial operator qualification course for the SUAS being flown.

TRAINING PROGRAM REQUIREMENTS

5-1. Refresher training. An operator entering refresher training will participate in training that consists of critical and unit-selected tasks. The operator must complete all training before he or she is designated MQ. The operator is designated MP during this training. Refresher training should include academic courses and practice of all tasks. During refresher training, the operator does not have semiannual proficiency and readiness test (S-APART) requirements in the SUAS in which the training is being conducted. The only requirements he or she has are those designated by the commander.

- The operator will complete the appropriate academic requirements IAW paragraph 3-12 and those tasks listed in this manual.
- All flight training in MP will be conducted by an MT.
- The operator will be evaluated by an MT.
- The operator will complete a qualified sortie at night (if applicable).

5-2. Mission training. The SUAS mission and operation of mission equipment is an integral part of being an operator qualified in a SUAS. This training must be completed before an operator is qualified to perform missions within his or her unit with a SUAS.

TRAINING PREREQUISITES

5-3. An operator returning to an operator position after having been prohibited/excused from flying duties for more than 180 consecutive days will receive refresher training. When an operator enters the unit's ATP with fewer than 180 consecutive days of non-operator duties, the commander may require him or her to undergo refresher training based on a records check or a PFE.

TASK CONSIDERATIONS

MASTER TRAINER

5-4. If an MT is part of a condition, he or she will be in a position close enough to assist the operator or assume control as the situation requires.

VISUAL METEOROLOGICAL CONDITIONS

5-5. Unless otherwise specified in the conditions, all in-flight training and evaluations will be conducted under VMC.

EMERGENCY PROCEDURES

5-6. The operator will know all underlined emergency procedures well enough to perform the required action from memory. Upon completion of the procedure, the checklist will be used to verify that no item was overlooked.

4892 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

LIMITATIONS

5-7. Operators will maintain operation within SUAS limitations at all times. Operation outside these limits, in other than an emergency situation, is unsatisfactory.

MISSION LEVEL TRAINING/EVALUATIONS

5-8. All ML training and evaluations will be conducted with an MT present and in a position to gain full access to the system controls.

TRAINING STRATEGY

5-9. The training strategy is developed using the outcome of the training assessment. It is then issued to subordinate commanders through the commander's training guidance (CTG).

NEAR-TERM PLANNING

5-10. Near-term planning is used for the monthly training schedule. The operations staff officer (S-3), with assistance from the MT/brigade aviation element (BAE) UAS technician—

- Reviews training aids, devices, simulators, and simulations and allocates training resources to specific trainers.
- Ensures that training events are well structured, efficient, realistic, safe, and effective.
- Must ensure that informal evaluation and feedback by trainers and senior leaders are continuous and that formal evaluations are included in training plans. (Evaluation documentation can range from annotated training and evaluation outlines to Combat Training Center (CTC) take-home packages.)

LONG-RANGE PLANNING

5-11. Long-range planning is used for the new annual training calendar. The S-3, with assistance from the MT/BAE UAS technician—

- Carefully studies the brigade CTG and key training events in which the unit will participate.
- Selects appropriate training scenarios with supporting operations plans from the training support packages.
- Coordinating with the brigade, division, and the military community, chooses training event dates that do not conflict with other key calendar events.

5-12. The tools used to develop a long-range training plan are the battalion training strategy, the brigade and division's CTG, and the brigade and division long-range training calendar—12 to 18 months out. These calendars may be viewed by subordinate commanders during their unit training planning.

QUARTERLY TRAINING CALENDAR

5-13. When preparing the quarterly training calendar, the S-3, with assistance from the MT/BAE UAS technician—

- Studies the brigade CTG and the battalion annual training calendar.
- Identifies, allocates, and coordinates short lead-time resources such as local training facilities.
- Pays particular attention to CTC lessons learned when developing training objectives and tasks to include in an field training exercise operation order.
- Allocates time on the aviation combined arms tactical trainer and other critical training resources.
- Cross-references each event with specific training objectives and coordinates with all supporting agencies, the battalion staff, and unit commanders.

4893 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

AIRCREW TRAINING PROGRAM

5-14. The ATP is an integral part of the commander's overall unit training program and should be briefed at each quarterly training brief. Proficient aircrews are essential to effective collective training. SUAS leaders/MTs must maintain a balance between individual, aircrew, and collective training. The ATP, mandated by AR 95-23, is a structured and prescriptive management and evaluation program focused on training Army aircrews. The ATP applies to all Army operators in operational flying positions. Developed IAW this TC and the appropriate ATM appendix, the ATP includes training of the base, mission and additional tasks necessary for the accomplishment of a unit's METL. In today's command operating environment, small unit leadership is critical to mission execution. Training must be tailored to ensure these elements are integrated into the training regime of our units. Leader supervision and participation at all levels is essential to the successful execution of the ATP.

5-15. The ATP, with the factors that affect it, is a major consideration in developing the long-range training plan. Consideration must be given to—

- Individual operator proficiency.
- Aircrew proficiency (battle-rostered crews).
- The unit maintenance program.
- Flight-hour allocation to supported units when SUAS training is conducted during supported unit missions.
- Individual and aircrew training that is usually accomplished while not in a support role; for example, emergency procedures training, and flight evaluations.
- Operator training accomplished in crew and collective simulators/simulations.

5-16. Units are required to have an ATP addressing specific requirements for conducting training, evaluation, assessment, and program revision. Commanders should use multi-echelon training objectives, scenarios, and standard training exercises (STXs) to facilitate the development, execution, and continual assessment of their training program. Scenarios and STXs for individual, crew, and collective training must be mutually supportive and progressive in intensity and complexity. Effective individual and crew training programs form the foundation for a SUAS battle-focused training program. These programs produce combat ready crews and are the basis for the unit's collective training program. Collective training must focus on combined arms/joint operations across the spectrum of the unit's METL. Limited resources, environmental restrictions, new and sophisticated aircraft mission equipment packages, and multiple contingency operations will all impact on the commander's ability to train and maintain proficiency at all levels.

4894 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

This page intentionally left blank.

Chapter 6

Individual Operator Training Record

The commander must ensure that a training record is prepared and maintained for each SUAS operator in an operational duty position assigned or attached to the unit. The ATP records system provides commanders with a comprehensive performance record on each operator in their unit. The required forms can be completed by hand using dark blue or black ink, by typewriter, or digitally. The forms are available at http://armypubs.army.mil. Aircrew training records are important quality control and standardization tools. They should be completed carefully, completely, and legibly. Examples of completed ATP forms with instructions are provided in figures 6-1 and 6-6 (pages 6-2 and 6-4); however, the examples are not intended to be all inclusive of required entries on the forms. Use the Remarks section of the forms and/or the comment slips to explain situations not clearly covered by the written guidelines.

INDIVIDUAL OPERATOR TRAINING RECORD REQUIREMENTS

6-1. The training record will be maintained as follows:

- DA Form 7122-R will be used. It will be maintained in the operator's unit training folder.
- Operators assigned or attached for flight duty will present their DA Form 7122-R to the commander or the commander's representative upon arrival into the unit.
- DA Form 4507-R (Crew Member Grade Slip) should be used to document training and evaluation flights.

DEPARTMENT OF THE ARMY FORM 7122-R

6-2. Purpose. DA Form 7122-R is used to permanently record all individual operator evaluations and summaries. It is also used to record any change in operator status or other significant events. General instructions for completing the form are as follows:

- Type or clearly print all entries in black, dark blue, or red ink (for out-of-sequence date entries only).
- For blocks that do not require an entry, enter "NA" for Not Applicable or a dash (—).
- To make minor corrections, use correction fluid/tape or neatly line through the incorrect information and add the correct information. Use procedures found in paragraph 6-3 to make major corrections.
- Keep entries as clear and concise as possible. Use standard abbreviations and acronyms.
- Significant related events that occur (aircraft qualification or MT course en route) during the time a crewmember departs the previous duty station and is integrated into a new ATP will be entered on DA Form 7122-R prior to the assignment entry.
- DA Form 7122-R is a two-page form; however, it is likely that one page will fill before the other. When one page of the form is filled, close out the other page of the form by drawing a diagonal line from the first unused block to the last unused block.
- Not every possible event or occurrence can be anticipated. If situations arise that are not covered by these instructions, use sound judgment and enter the event in the most logical manner.

6-3. Corrections to DA Form 7122-R may be needed for several reasons. Careful and timely entering of events as they occur will eliminate the need for corrections.

4896 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

- Out-of-sequence events. If an event is not entered at the proper time and one or more events have been recorded, enter the event as you would any other event on the next available line. Use red ink when entering the date only (to include year) for the out-of-sequence event.
- Unusable form. If enough mistakes accrue to make the form unusable, transcribe the data to a new form. Place a diagonal line across the front of the unusable form, label it "transcribed," and retain this copy of the form (permanently) under the current form.

Note. Do not destroy or discard any DA Form 7122-R that contains an entry.

DA FORM 7122-R INSTRUCTIONS

6-4. Instructions for completing DA Form 7122-R are as follows.

Crewmember Training Record, Page 1

- **Sheet Number.** Number each sheet in numerical order.
- **Name.** Enter the crewmember's full name (last, first, and middle initial). If reproducing the form on two separate sheets of paper, enter the crewmember's name on the first line of the second sheet, in the Remarks area, followed by the sheet number with which it corresponds.
- **PID.** Until further guidance leave this blank.
- **Rank.** Enter the crewmember's rank.
- **Birth Month.** Enter the crewmember's birth month. **Date.** Enter the day, month, and year of the event. After the first entry, it is acceptable to omit the year until entry of the first event of the following year. If an entry is out of chronological order, only the date will be in red and the year must be included.
- **A/C.** Enter the alphanumeric designation of the appropriate aircraft (for example, RQ-11A or RQ-11B). If the event was performed solely in a flight simulator, enter the simulator designation (RQ-11B SIM or VAMPIRE SIM).
- **Event.** Enter a short summary of the event on one line. Record events listed below:
  - Unit assignments and reassignments. Reassignment within the unit not requiring a DA Form 759 (Individual Flight Record and Flight Certificate-Army) closeout will be treated as a change of duty.
  - Start and completion of time-limited training programs, such as, ML progression or MT qualification.
  - Start and completion of DA qualification courses, both flying and non-flying.
  - Completion of significant training or retraining programs. (Summarize the event on one line.)
  - All evaluations.
  - MT designation.
  - Completion of the written examination.
  - All proficiency flight (oral or written) evaluations. (Specify the type of evaluation; for example a no-notice evaluation, the flight portion of a commander's evaluation, or currency evaluation.)
  - All requests for waivers or extensions and their disposition.
  - Involvements in any class A, B, C, or D accident or incident and the results of any post accident evaluation (if given).
- **Duty.** Not applicable.
- **Day (D), Night (N), Night Google (s) (NG), Night System (NS), Weather (W), Hood (H), and Simulator (Sim).** For the event being recorded, enter the number of qualified sorties conducted under the appropriate flight modes/conditions. The sortie number entered will be the sorties flown on any single flight event (such as an evaluation) or the total sorties flown in multi-flight training programs.

4897 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

- **Seat.** Not applicable.
- **Recorded By.** MTs, trainers, operations personnel and others when authorized by the commander will enter their first initial, last name, rank and duty position. If the event was an evaluation and someone is recording it other than the MT, record the MT's name in the remarks section.
- **GR (grade).** If the event was graded, enter an "S" (Satisfactory) or a "U" (Unsatisfactory). For an unsatisfactory evaluation, state the specific tasks the crewmember performed unsatisfactorily and any restrictions imposed due to the failure. Provide a recommendation to the commander for retraining and re-evaluation.
- **CM Init (crewmember initials).** Brief the crewmember on the entry and ensure that the crewmember understands any change in status. Crewmembers will then initial this block. A crewmember's initials indicate that the crewmember is aware of the entry on the form and any remarks and understands any change in status. The crewmember will immediately initial any entry resulting in a change of status, such as, an unsatisfactory evaluation or a suspension. The crewmember will initial routine entries, such as, assignment to a unit or satisfactory evaluations, as soon as practical.
- **Rmk (remarks).** Enter "Yes," "Y," "No," or "N" in this column to show whether comments are entered in the Remarks section regarding the entry. Do not enter "NA" in this column or leave it blank.

Crewmember Training Record, Page 2

- Date. Include date pertinent information was recorded in remarks. Enter the date in the same format used on the front of the form.
- Remarks. Record pertinent information not shown on the front of the form in this section. Do not restate information entered on the front of the form, for example, "This was a satisfactory evaluation." There is no single correct way of entering remarks. However, they should be clear, concise, and specific. When entering remarks, use standard abbreviations and acronyms or logically shortened words. If the remarks require more than one line, do not repeat the date on the second or subsequent line(s). Remarks that could be entered include the issuance of an MT qualification by an MT and an explanation of extension for completion of ATP requirements.

6-5. Only the following events recorded on the DA Form 7122-R require the commander's signature:

- Nonmedical suspension.
- ML designation after failure of a hands-on performance test or a training deficiency.
- Extensions or waivers.
- Return to previous duties after nonmedical suspension or ML designation after failure of a hands-on performance test or a training deficiency.

Note. The commander, pertaining to the training folder, is defined as the commander responsible for the ATP. Waiver and extension authority is IAW AR 95-23, local regulations, and SOPs. The appropriate commander will sign the DA Form 7122-R, page 2, when required. Memorandum for Record granting extensions or waivers signed by the commander will be retained in the miscellaneous section of the training folder until the end of the ATP year.

DA FORM 7122-R SAMPLE

DEPARTMENT OF THE ARMY FORM 4507-R

6-7. The DA Form 4507-R will be filed on the right side of the individual aircrew training folder (IATF) until training has been completed and the event has been documented on the DA Form 7122-R. Once the event has been entered on DA Form 7122-R, then DA Form 4507-R will be removed from the IATF.

DA FORM 4507-R INSTRUCTIONS

6-8. Instructions for completing the form are as follows.

DA Form 4507-R, Page 1

- **Name.** Enter the crewmember's name (last, first, middle initial).
- **Rank**. Enter the crewmember's rank.
- **PID.** Enter the individual's SUASMAN identification.
- **Unit.** Enter the unit to which the crewmember is assigned.
- **Purpose.** Enter the purpose of the training or evaluation using standard phraseology; for example, refresher training or AC evaluation.
- **Aircraft Type.** Enter the alphanumeric designation of the aircraft or flight simulator; for example, MQ-5B, RQ-7B, MQ-1C.
- **Date Started.** Enter the date on which the flight training program starts.
- **Must Complete By.** If the training program is time limited, enter the date on which the crewmember must complete it. If the date changes, line through the original date and enter the new date above it. Explain the change in the Comments section.
- **Date.** Enter the day, month, and year of the flight.
- **Flight Data.** This form provides a cumulative record of the time flown under those flight modes normally requiring minimum amounts. Record all flight time in hours and tenths of hours.
  - **Time Today.** Enter the total time flown today.
  - **Cumulative Time.** Record the total flight time accrued to date.
  - **Day Flight-Today.** Enter the time flown today under day flight conditions. For flights conducted under other than day flight conditions, enter the applicable flight mode or condition in the space provided. Then record the time flown today for that flight mode or condition.
  - **Day Flight-Cumulative.** Record the total time accrued under day flight conditions. For flights conducted under other than day flight conditions, enter the applicable flight mode or condition in the space provided. Then record the total flight time accrued to date for that flight mode or condition.
  - **Duty Position.** Enter the crewmember's duty position for the flight.
  - **Seat Position.** Enter the crewmember's seat position for the flight.
  - **Overall Grade.** Enter either "S" or "U" in the overall grade block after the crewmember completes the flight. This grade reflects the MT's/trainer's overall assessment of the flight. If the overall flight is graded a "U", a comment is required on DA Form 4507-2-R.
  - **Crewmember Initials.** Have the crewmember initial the grade slip to certify that the crewmember has been debriefed. The initials do not mean that the crewmember agrees with the results.
  - **Trainer or Evaluator Name, Rank, and Duty Position.** Enter the trainer's or the evaluator's first initial, last name, rank, and duty position.

DA Form 4507-R, Page 2

- **Date.** Enter date of pertinent comments.
- **Comments.** Enter pertinent comments on DA Form 4507-R. Enter sound, objective comments. If the overall flight or any individual task is graded "U", a comment is required. For unsatisfactory tasks, indicate which standards were not met and any other appropriate remarks.

4901 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

These comments are important for reference by other trainers or evaluators during future training or evaluation.

DA FORM 4507-1-R INSTRUCTIONS

6-12. Instructions for completing the form are as follows.

- **Trainee's/Examinee's Name.** Enter the examinee's name (last, first, middle initial).
- **Select.** If the form is tailored to the training or evaluation being conducted, use as desired. If the form lists all base and mission/additional tasks, place an "X" in the selection column by each task that is mandatory for the training program or evaluation underway based on the guidance in the applicable ATM, this training circular, the commander's task list, the unit SOP, and other documents.

4904 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

- **Page No.** Enter the number of this page.
- **No. Pages.** Enter the total number of DA Forms 4507-1-R used.
- **Maneuver/Procedure.** Enter the task number followed by the task title as required by the unit's ATP. Units may list all tasks required by the commander's task list. Another option is to develop separate forms for each training program; for example; night goggle refresher training, RL progression, and mission training. Units may also use a highlighter pen or any other suitable method to track completion of tasks in different modes. Task titles may be abbreviated to fit within the space provided.
- **Date.** Enter the day, month, and year of the flight. It is acceptable to have multiple entries for the same date to specify tasks trained/evaluated in different flight modes. In the blocks under the date, the evaluator/trainer or unit trainer grades each task performed. An unsatisfactory grade "U" requires a brief description of the deficiency in the comments section of DA Form 4507-2-R (Continuation Comment Slip). Place a diagonal (/) in the grade blocks for all maneuvers or procedures not performed. When three or more consecutive tasks are not graded, place a diagonal line in the first and last task and connect the two with a straight vertical line.

DEPARTMENT OF THE ARMY FORM 4507-2-R

6-13. The DA Form 4507-2-R is used to record comments and explain DA Form 4507-R and DA Form 4507-1-R entries, as appropriate.

Chapter 7

Composite Risk Management

Tough, realistic training conducted to standard is the cornerstone of Army warfighting skills. The battle-focused training environment places stress on both Soldiers and their equipment, creating a high potential for loss. As training realism increases, so does the potential for loss. If risk is not reduced, personnel and equipment losses caused by training mishaps pose a serious drain on warfighting assets. Accidental losses during training are no different from combat losses; in either case, the assets are gone. Commanders must find ways to protect individuals and equipment from accidents during realistic training to prepare for war. Guidance on composite risk management (CRM) is contained in ADP 5-0, FM 5-19, and AR 385-10.

GENERAL

7-1. An effective risk management program is vital at all levels of operations and requires the personal attention and participation of unit commanders and leaders all along the chain of command. The protection of Soldiers and their weapon systems is a way of life in the Army. An effective ATP, thoughtfully planned in conjunction with appropriate regulations and guidance, is arguably the most important factor in any unit's safety program once it is embraced by every Soldier in the unit. Flying "by the book" does not hinder, but actually enhances, a unit's battle focus. The crawl/walk/run approach to training is imperative to reduce risks, as is the active participation of commanders at all levels of the training process.

COMPOSITE RISK MANAGEMENT CONCEPT

7-2. CRM is the decision-making process for identifying hazards and mitigating risks across the entire spectrum of Army missions, functions, operations, and activities. It is a holistic assessment, blending tactical and threat-based risk management with accidental, hazards-based risk management. CRM is not a stand-alone process, a paperwork drill, or an add-on feature to planning. Rather, it is used as a fully integrated element of planning and decision making. It may also be executed intuitively in situations that require hasty planning or immediate action. CRM should be viewed as part of the military art interwoven throughout the Army's military decision- making and training management cycles. CRM follows a process which personnel of all ranks must continually use. The CRM steps are shown in figure 7-1, page 7-5.

7-3. Using the CRM process, leaders identify the hazards that may cause mission degradation and loss of unit combat readiness and effectiveness. These include those hazards that may cause injury and/or death to personnel or damage and/or destruction of equipment. A commander should then determine the possible impact of each hazard on the mission, take action to minimize or eliminate the hazards, then execute the mission or modify the mission to further reduce risk.

7-4. CRM is not a restrictive measure. It is a conscious analysis of the mission itself, possible courses of action, and the implementation of appropriate controls to ensure any risk is reduced or eliminated.

7-5. The CRM process includes several terms all leaders should know. These terms are—

- CRM process. The process of identifying and controlling hazards to protect the force.
- Control. Any action taken to eliminate hazards or reduce their risk.
- Hazard. Any real or potential condition that can cause the loss of an asset. These losses include injury, illness, and death of personnel; damage to or loss of equipment or property; and mission degradation.

4908 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

- Risk. The chance of hazard or bad consequences. Exposure to a chance of injury or loss. Risk level is expressed in terms of hazard probability and severity.
- Exposure. The frequency and length of time subjected to a hazard.
- Probability. The likelihood that an event will occur.
- Severity. The expected consequence of an event in terms of the degree of injury, property damage, or other mission impairing factors that could occur.
- Risk assessment. The identification and assessment of hazards.
- Residual risk. Any anticipated level of risk remaining after controls have been identified and selected for hazards that may result in loss of combat power.
- Risk decision. Accept or not accept the risk(s) associated with an action; made by the commander, leader, manager, or individual responsible for performing that action.

7-6. The standard for CRM is leadership at the appropriate level of authority making informed decisions to control hazards or accept risks. Leaders are responsible and accountable for assessing their operation as a total system.

7-7. The degree of risk determines the level of decision authority. When resources to reduce risk to an acceptable level are not available, the risk issue must be elevated to the next higher command. This process continues until the information is presented to the level of command that has the resources and authority to eliminate the hazard or control the risk to an acceptable level. In this manner, a conscious and informed decision is made to either commit the resources to control the hazards or to accept the risk.

RESPONSIBILITIES

7-8. CRM is not complex, technical, or difficult and is not limited to the brigade and battalion commanders. It is a simple decision making process and a way of "thinking through a mission" to balance mission demands against known risks. Trainers/evaluators can maintain realism in training accomplishment through CRM. In peacetime, the process must be deliberate, continuous, and must become second nature to those responsible for planning, approving, or leading activities. In combat, the process is no less deliberate, though risks may be accepted as dictated by the mission priority.

LEADERS

7-9. What is the commanders responsibility, at all levels? Who establishes what risk: extremely high (E), high (H), moderate (M), or low (L)?

7-10. Managing risks is a leadership responsibility. At the crewmember level, MTs and instructors are the principal risk managers. Planning must incorporate consideration for known hazards and must address appropriate control measures to minimize exposure to these hazards. While CRM is introduced in the planning phase of a mission, for MTs, CRM responsibilities are not complete until the mission debriefing is complete.

7-11. To meet these responsibilities, leaders do not accept unnecessary risk. If the risk can be eliminated or reduced and the mission can still be accomplished, the risk is mitigated and acceptable. Find ways to mitigate the risk (for example, change the crew mix, change the mission execution time, provide additional preparation and training, and add additional supervision) that will still allow completion of the mission. Once hazards are identified and controls recommended, compare and balance the residual risk against the mission expectation.

7-12. Pre-mission. The commander, or other designated risk approval authority, decides if the controls are sufficient to accept the risk. If the risk is excessive, the commander can direct additional control measures, modify controls, request the next higher commander's involvement, or reject the mission.

7-13. During mission execution. The commander cannot always be available to make every risk decision. In the aircraft, when the situation, time, or other factors do not allow for the commander's decision, the MTs, instructors, or other unit leaders become the primary risk managers. In such cases, they should use the commander's guidance, their professional experience, unit SOPs, ATMs, regulations, current situation,

4909 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

developing conditions, and so forth as the basis upon which they formulate control measures. They should evaluate unexpected hazards that are encountered during the course of the mission and apply the appropriate control measures.

7-14. Make risk decisions at the proper level. Decisions made at the proper level eliminate the involvement of commanders not normally involved in the mission or commanders not authorized to accept the level of risk. ACs must know the appropriate level of approval authority based on the level of risk. The risk approval authority will vary between units and risk approval authority must at all levels be capable of mitigating risk or accepting that level of risk.

7-15. Weigh the risks versus the benefits. The benefits gained by accepting a residual risk must clearly outweigh the potential cost in terms of life, limb, or equipment loss should an incident occur.

7-16. Identify controls. Integrate CRM into all stages of all operations. Integration begins with the pre-mission planning and continues through the completion of the mission debriefing. Consider CRM as contingency planning. The commander and staff should look at factors that could cause the mission to fail (cause loss of life, limb, or equipment) and implement controls to minimize that probability. During the debriefing, unexpected hazards for a completed mission then become expected hazards for follow-on missions.

7-17. While crewmembers are not specifically members of the unit staff, they normally provide input to the battalion staff through their company commander. During operations, the staff normally does not occupy a crew station, but through their work, a significant portion of CRM does occur before any start switch is pressed. Some functions that the staff performs, relative to CRM, are as follows:

- Assist in the planning and identification of hazards for operations.
- Integrate CRM into operations plans and orders. In developing plans, the staff evaluates the risks, recommends controls to minimize the risks, and provides the commander with an assessment of the effectiveness of the imposed controls. In training situations, the staff—
  - Advises the commander of the controls that impact on training realism, so the commander can make the risk acceptance decision.
  - Evaluates imposed safety restrictions to ensure optimal training benefit is achieved without unnecessary restrictive measures applied.
  - Assess the operational risk. Using mission, enemy, terrain and weather, troops and support available, time available, and civil considerations factors to identify the risk to mission accomplishment, the staff begins to assess operational risks. The most important consideration is the outcome of the operation for the unit, higher headquarters, and adjacent units. Risk analysis is formulated using a course of action that is developed along the spectrum of frequent to seldom event occurrence. The staff reviews and expands or refines the list throughout the planning and execution of the exercise. The staff then evaluates the possible consequences of those risks from catastrophic to marginal, for example, the staff plans a multi-aircraft mission to airlift personnel or supplies. If the weather forecast is for marginal conditions, part of the planning should include the possibility of weather conditions degrading during the mission.

7-18. Controls the staff might propose are—

- Reinforcing those sections of the SOP pertaining to adverse weather.
- Briefing crews regarding the current and forecast adverse weather and the possible courses of action selected by the commander.
- Planning alternate transportation.
- Designating recovery airfields.

7-19. The staff should also consider the possibility of additional personnel or equipment showing up for transport than were expected. How will the crews accommodate this change? What impact will the additional payload have on the aircraft performance? Controls could include maximums on payload, additional sorties, backup aircraft, or other controls that would ensure mission accomplishment with minimum risks. There are additional hazards that could be identified in this example.

4910 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

SAFETY OFFICER

7-20. The safety officer—

- Is an integral part of the CRM, planning process.
- Is a special staff officer who advises the commander and staff on safety requirements and recommends controls to minimize risks.
- Participates in all phases of the military decision-making process to ensure CRM follows the commander's intent.
- Assists all staffs in integrating the CRM process into other staff functions.
- Assists the command in supervising operations to ensure application and adherence to imposed controls and provides feedback on the effectiveness of the program.

CREWS

7-21. Crewmembers are a critical part of the CRM process. They perform the mission and their involvement in the planning phase is crucial to identification of hazards and controls. Crewmembers must clearly understand the controls implemented to mitigate risks. During mission execution, crewmembers must perform tasks and implement control measures to standard. The employment of good crew coordination is paramount to identifying unexpected hazards (for example enemy situation, wires, and weather) and to continuously refine controls during the mission.

INDIVIDUALS

7-22. Self-discipline is critical to mission accomplishment and to an effective CRM program. The best CRM plan is worthless if the individuals performing the mission do not adhere to established controls or do not perform the tasks to standard. Individuals performing a mission are also responsible for performing CRM. While performing the mission, conditions, hazards and risks change and by necessity, CRM controls may change. The individual must constantly assess the conditions and continuously apply the principles of CRM to ensure minimum risk to themselves, fellow Soldiers, the aircraft, and the mission.

COMPOSITE RISK MANAGEMENT TRAINING

7-23. Commanders must conduct CRM training for their unit. Training should emphasize the process and must reinforce the philosophy that Soldiers—crewmembers and ground personnel—are responsible for performing CRM; without a full range of participation, commanders may not make an informed decision.

COMPOSITE RISK MANAGEMENT PROCESS

7-24. The CRM process is comprised of the following actions: identify hazards, assess risks, develop controls and risk decisions, implement controls, and supervise and evaluate (figure 7-1, page 7-5).

4911 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

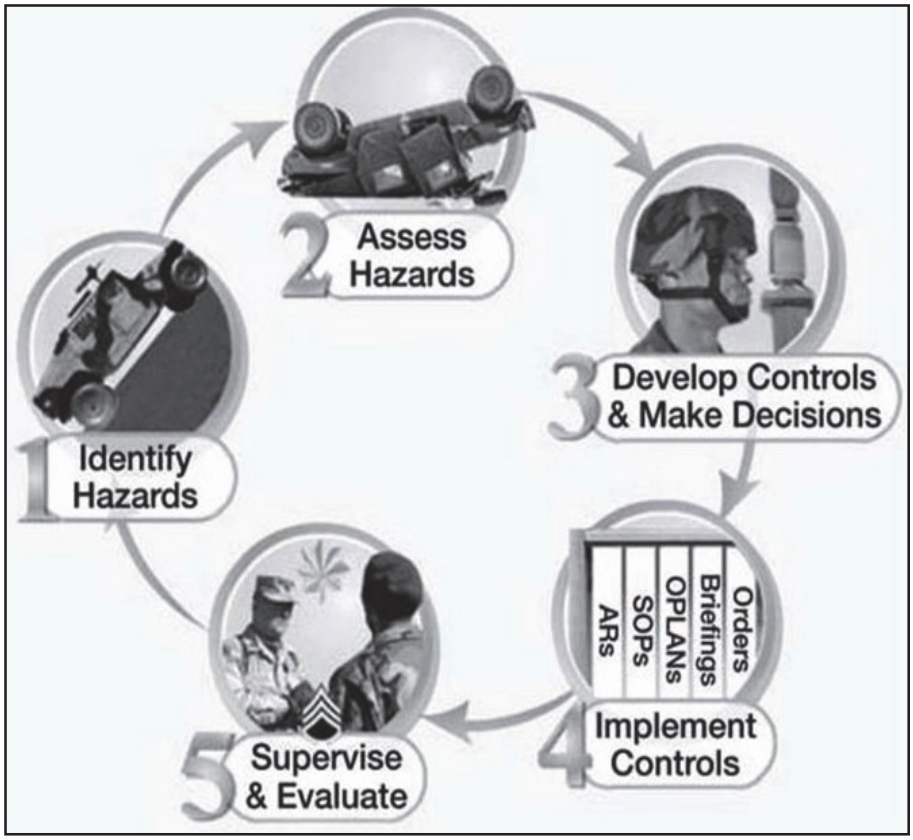

Figure 7-1. Composite risk management steps

STEP 1-IDENTIFY HAZARDS

7-25. Identify the major events in the mission and list chronologically. This will help identify all hazards associated with the specified as well as implied tasks.

7-26. Complete a preliminary hazard analysis of operational events. This identifies, as early as possible, the obvious hazards expected during the mission. Early identification provides more flexibility in addressing the hazards and allows more options for controls, which maximizes a leader's ability to complete the mission.

STEP 2-ASSESS RISKS

7-27. Determine the level of risk associated with each hazard. Commanders should ask, "Can the hazard result in a fatality, damage to equipment, or mission failure?" The degree of risk associated with each particular hazard will help define the level of controls necessary. For example, risks associated with a single operator, night, tactical flight might include lack of situational awareness, inadvertent weather, over tasking, and degraded performance, while risks associated with a multi-ship mission in the same environment would include mid air collision as well. (These are usually contained in the unit SOP or designated by the command.) Controls for the previous example may include a day route reconnaissance to establish minimum weather requirements, change the crew mix, adjust the mission execution time, conduct crew awareness briefings on recovery procedures, and single operator launch training. For multi-ship operations, controls might also include a rehearsal to practice deconfliction procedures and to specify separation distances and altitudes. Consider using the METT-TC format as another means to assess risks. Leader's can subjectively determine the likelihood and extent of accidental loss based on this type of analysis.

4912 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

STEP 3-DEVELOP CONTROLS AND MAKE DECISIONS

7-28. All hazards cannot be eliminated. There is a point at which the command must accept the risks and direct the mission to continue, modify the mission, or abort the mission. This is not to say that the CRM process stops. The CRM process is a continual process. There may come a time during a mission when an opportunity exists to eliminate a particular risk. That opportunity might not be apparent if the CRM process is not continual. The intent is to mitigate the probability of an accident or the severity of the consequences with prudent controls whenever the risk is evident. For example, an experienced ground crew on a night launch with sufficient personnel and good illumination still faces the possibility of engine malfunction, human error, or propeller strikes. The command has identified the controls, but cannot eliminate all the risks; it accepts the residual risks, in this case, as necessary and unavoidable.

7-29. In identifying and implementing controls, commanders should—

- Eliminate the hazard. This may include changing the crew, mission time (day versus night), equipment, or aircraft type.
- Guard or control the hazard. For flight operations, this might include routine radio calls to operations, crew mix, safety aircraft, emergency training, and minimum crew requirements.
- Change operational procedures to limit exposure to hazards, for example, minimize the number of systems or personnel or limit exposure to a particular hazard.
- Train and educate personnel in hazard recognition and avoidance. Some good examples include the limitations of night vision and the known performance and operational limits of the aircraft.
- Enforce the use of protective clothing or equipment that will minimize injury and damage potential. Examples include helmets, gloves, hearing protection, fire protected clothing, ground vehicle emergency kits, first aid training, and backup gear. Use color coding and signs to alert personnel of hazards—safety lanes in hangars, stairs, curbs, marking on aircraft for tail rotors, and arming and refueling point markings.

STEP 4-IMPLEMENT CONTROLS

7-30. Integrate controls into the planning. Ensuring awareness of the hazards and controls, from the commander through the individual(s) performing the task, is essential to success.

STEP 5-SUPERVISE AND EVALUATE

7-31. Leaders must enforce the controls and standards. The best CRM program is ineffective if the command does not enforce the controls. AOs are the leaders during SUAS missions and upholding standards must be a high priority. The most common cause of accidents is the failure of an individual to adhere to standards or a failure of the command to enforce a known standard.

7-32. Leaders must supervise activities of subordinate units. Battalion will supervise company operations; the company will supervise platoon operations, and so forth. Supervising a subordinate unit does not imply interference. Only by seeing the character of operations will leaders fully appreciate risk implications or the effectiveness of the CRM program.

7-33. Leaders at all levels are responsible for supervising operations. From private to general, all Soldiers can, and must, share in the responsibility for supervising. The purpose of this supervision is to ensure the identification of hazards and that controls are followed. Additionally, as conditions change, the supervisor continually evaluates the effectiveness of established controls to ensure successful completion of the mission.

RISK ASSESSMENT TOOLS

7-34. Using risk assessment tools, such as matrices and diagrams, is valuable during the planning stage of a mission. These tools do not cover the entire CRM process, but they do provide a systematic approach to identifying and reducing risk. However, do not allow the risk assessment tools to become the overriding concern of the CRM process. Tools merely provide a measurement for leaders to gauge risk and control effectiveness.

4913 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Note. Risk assessment tools do not make decisions. Leaders make decisions.

7-35. Probability is the likelihood of an event. This is your estimate, given what information you know and what others have experienced. The probability levels estimated for each hazard are based on the mission, course of action, or frequency of a similar event. For the purpose of CRM, there are four levels of probability—frequent, likely, occasional, and seldom (figures 7-2 and 7-3).

PROBABILITY-FREQUENT
Occurs very often (known to happen regularly). Given 500 or so exposures to the hazard, expect that it will definitely happen to someone. Two examples of frequent occurrences are rollovers and rear-ending a vehicle.
PROBABILITY-LIKELY
Occurs several times (a common occurrence). Happens every 1,000 or so exposures. Examples are IEDs, wire strikes for aircraft, controlled flight into terrain, and accidental discharges
PROBABILITY-OCCASSIONAL
Occurs sporadically (but is not uncommon). You may or may not get through your deployment without it happening. Two examples are UXO and fratricide.
PROBABILITY-SELDOM
Remotely possible (could occur at some time). Usually several things must go wrong for it to happen. Two examples are heat-related death or electrocution.

Figure 7-2. Probability chart

PROBABILITY / ***SEVERITY***	***FREQUENT***	***LIKELY***	***OCCASSIONAL***	***SELDOM***
CATASTROPHIC	E	E	H	M
CRITICAL	E	H	H	L
MARGINAL	H	M	L	L
E=extremely high……..…..Loss of ability to accomplish the mission.				
H=high…..……..……..Significant degradation of mission capabilities.				
M=moderate…….……..…Expected degraded mission capabilities.				
L=low……...…….……..Little or no impact on accomplishing the mission.				

Figure 7-3. Risk assessment matrix

7-36. Catastrophic is defined as follows:

- Loss of the ability to accomplish the mission or mission failure.
- Death or permanent total disability (accident risk) of personnel.
- Loss of major or mission-critical system or equipment.
- Major property (facility) damage.
- Severe environmental damage.
- Mission-critical security failure.
- Unacceptable collateral damage.

7-37. Critical is defined as follows:

- Significantly (severely) degraded mission capability or unit readiness.
- Permanent partial disability, temporary total disability exceeding 3 months time (accident risk).
- Extensive (major) damage to equipment or systems.
- Significant damage to property or the environment.
- Security failure.
- Significant collateral damage.

4914 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

7-38. Marginal is defined as follows:

- Degraded mission capability or unit readiness.
- Minor damage to equipment or systems, property, or the environment.
- Lost day due to injury or illness not exceeding 3 months (accident risk).
- Minor damage to property or the environment.

7-39. One matrix cannot include all of the hazards of every mission, nor can one matrix apply to all units. Commanders must determine the usefulness and content of any risk assessment tool. Commanders must consider a number of basic principles when they use these tools.

Note. Additional risk management tools can be found at https://safety.army.mil.

7-40. Commanders must remember—

- Adding the numbers up and finding the right level of command to accept the risk is not CRM.
- The risk assessment matrix is most valuable during mission planning.
- Each element of the matrix represents a specific hazard that, in the risk assessment process, translates into risk.

7-41. Commanders should review the unit METL as they develop their risk assessment matrices. They should assess each METL task from the highest risk to the lowest risk. Commanders should then select the task(s) or task elements upon which they personally want to initiate risk reduction action and approval. Their risk assessment matrices should clearly show these critical elements.

7-42. Commanders should include additional items when developing the risk assessment matrix, when applicable. An example of a high-risk mission is a relief on station with an inexperienced crew that just arrived in country and restricted visibility caused by fog. The factors that play the biggest role in this example could be lack of experience and the new area of operations. Commanders may wish to refer these types of mission elements to the next higher commander for risk reduction or acceptance, because the effect of these factors greatly increases mission risk.

4915 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Appendix A
Small Unmanned Aircraft System Tasks

A-1. Table A-1 provides a list of SUAS tasks.

Note. Environmental considerations. For operations conducted in conditions such as hot/cold weather, turbulence, rain/thunderstorm, desert/sand/dust, or wind, reference system limitations in the operator's manual, AR 95-23, and FM 3-04.203.

Table A-1. Small unmanned aircraft system task list

Prepare the SUAS for an Aerial Mission	
Task	***Description***
1001	**Title:** Assemble SUAS
	Condition: Given an SUS, TM 1-1550-695-13&P, TM 1-1550-695-CL, and local SOP.
	Standard: Assemble an SUAS IAW TM 1-1550-695-13&P, TM 1-1550-695-CL, and local SOP.
1002	**Title:** Assemble Ground Control Station (GCS)/Ground Control Unit (GCU)
	Condition: Given an SUAS GCS/GCU, TM 1-1550-695-13&P, TM 1-1550-695-CL, and local SOP.
	Standard: Assemble an SUAS GCS/GCU IAW TM 1-1550-695-13&P, TM 1-1550-695-CL, and local SOP.
1003	**Title:** Assemble Remote Video Terminal (RVT)
	Condition: Given a SUAS RVT, TM 1-1550-695-13&P, TM 1-1550-695-CL, and local SOP.
	Standard: Assemble an SUAS RVT IAW TM 1-1550-695-13&P, TM 1-1550-695-CL, and local SOP.
1004	**Title:** Operate SUAS Battery Charger
	Condition: Given an SUAS Unmanned aircraft Battery Charger, TM 1-1550-695-13&P, TM 1-1550-695-CL, and local SOP.
	Standard: Perform Battery charging with an SUAS Unmanned aircraft Battery Charger IAW TM 1-1550-695-13&P, TM 1-1550-695-CL, and local SOP.
Prepare the SUAS for Flight Operations	
Task	***Description***
1005	**Title:** Perform Airspace Management Coordination
	Condition: Given a requirement to conduct airspace management coordination, AR 95-23, FM 3-04.155, TM 1-1550-695-13&P, TM 1-1550-695-CL, and local SOP.
	Standard: Perform Airspace Management Coordination IAW AR 95-23, FM 3-04.155, TM 1-1550-695-13&P, TM 1-1550-695-CL, and local SOP.
1006	**Title:** Complete SUAS Preflight Mission Planning
	Condition: Given a mission requirement, an SUAS, TM 1-1550-695-13&P, TM 1-1550-695-CL, FM 3-04.155, and local SOP.
	Standard: Complete SUAS Preflight Mission Planning IAW TM 1-1550-695-13&P, TM 1-1550-695-CL, FM 3-04.155, & local SOP.
1007	**Title:** Complete a SUAS Crew Mission Briefing
	Condition: Given a requirement to conduct Crew Mission Briefing, an SUAS, TM 1-1550-695-13&P, TM 1-1550-695-CL, FM 3-04.155, and local SOP.
	Standard: Complete SUAS Crew Mission Briefing IAW TM 1-1550-695-13&P, TM 1-1550-695-

4916 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Table A-1. Small unmanned aircraft system task list

	CL, FM 3-04.155, and local SOP.
1008	**Title:** Complete SUAS Preflight Checks
	Condition: Given a requirement to conduct Preflight Checks, an SUAS, TM 1-1550-695-13&P, TM 1-1550-695-CL, FM 3-04.155, and local SOP.
	Standard: Complete SUAS Preflight Checks IAW TM 1-1550-695-13&P, TM 1-1550-695-CL, FM 3-04.155, and local SOP.
Conduct SUAS Flight Operations	
Task	***Description***
1009	**Title:** Respond to Warning Displays
	Condition: Given an SUAS and displayed warning(s), TM 1-1550-695-13&P, TM 1-1550-695-CL, FM 3-04.155, and local SOP.
	Standard: Respond to Warning Displays of an SUAS IAW TM 1-1550-605-13&P, TM 1-1550-695- CL, FM 3-04.155, and local SOP.
1010	**Title:** Complete Before Takeoff Checks
	Condition: Given a requirement to conduct Preflight Checks, an SUAS, TM 1-1550-695-13&P, TM 1-1550-695-CL, FM 3-04.155, and local SOP.
	Standard: Complete SUAS Preflight Checks IAW TM 1-1550-695-13&P, TM 1-1550-695-CL, FM 3-04.155, and local SOP.
1011	**Title:** Launch Unmanned aircraft
	Condition: Given a requirement to launch an SUAS unmanned aircraft, an SUAS, TM 1-1550-695-13&P, TM 1-1550-695-CL, FM 3-04.155, and local SOP.
	Standard: Launch an SUAS unmanned aircraft IAW TM 1-1550-695-13&P, TM 1-1550-695-CL, FM 3-04.155, and local SOP.
1012	**Title:** Complete Unmanned aircraft In-Flight Operations
	Condition: Given an SUAS unmanned aircraft inflight, TM 1-1550-695-13&P, TM 1-1550-695-CL, FM 3-04.155, and local SOP.
	Standard: Complete SUAS inflight operations IAW TM 1-1550-695-13&P, TM 1-1550-695-CL, FM 3-04.155, and local SOP.
1013	**Title:** Complete Before Landing Checks
	Condition: Given a requirement to land an SUAS unmanned aircraft, TM 1-1550-695-13&P, TM 1-1550-695-CL, FM 3-04.155, and local SOP.
	Standard: Complete Before Landing Checks for an SUAS unmanned aircraft IAW TM 1-1550-695-13&P, TM 1-1550-695-CL, FM 3-04.155, and local SOP.
1014	**Title:** Complete Autoland Procedure
	Condition: Given a requirement to autoland an SUAS unmanned aircraft, TM 1-1550-695-13&P, TM 1-1550-695-CL, FM 3-04.155, and local SOP.
	Standard: Complete Autoland Procedures for an SUAS unmanned aircraft IAW TM 1-1550-695-13&P, TM 1-1550-695-CL, FM 3-04.155, and local SOP.
1015	**Title:** Complete Post Flight Procedures
	Condition: Given a requirement to perform post flight procedures on a landed SUAS unmanned aircraft, an SUAS, TM 1-1550-695-13&P, TM 1-1550-695-CL, FM 3-04.155, and local SOP.
	Standard: Complete Post Flight Procedures for an SUAS unmanned aircraft IAW TM 1-1550-695-13&P, TM 1-1550-695-CL, FM 3-04.155, and local SOP.
1016	**Title:** Respond to an Emergency
	Condition: Given an SUAS and an emergency(s), TM 1-1550-695-13&P, TM 1-1550-695-CL, FM 3-04.155, and local SOP.
	Standard: Respond to an Emergency of an SUAS unmanned aircraft IAW TM 1-1550-695-13&P, TM 1-1550-695-CL, FM 3-04.155, and local SOP.
1017	**Title:** Complete Remote Launch Procedures

4917 DISTRIBUTION A: NOT FOR MISUSE IN SUPPORT OF IDIOTIC THEORIES| | VIOLATORS GO STRAIGHT TO GITMO FOR BALL ZAPPING

Table A-1. Small unmanned aircraft system task list

	Condition: Given a requirement to remote launch an SUAS unmanned aircraft, an SUAS, TM 1-1550-695-13&P, TM 1-1550-695-CL, FM 3-04.155, and local SOP.
	Standard: Complete Remote Launch Procedures for an SUAS unmanned aircraft IAW TM 1-1550-695-13&P, TM 1-1550-695-CL, FM 3-04.155, and local SOP.
1018	**Title:** Complete Hand-off Procedures
	Condition: Given a requirement to complete Handoff Procedures with an SUAS unmanned aircraft, an SUAS, TM 1-1550-695-13&P, TM 1-1550-695-CL, FM 3-04.155, and local SOP.
	Standard: Complete Handoff Procedures with an SUAS unmanned aircraft IAW TM 1-1550-695-13&P, TM 1-1550-695-CL, FM 3-04.155, and local SOP.
Perform Post-Flight Operations	
Task	***Description***
1019	**Title:** Disassemble and Store System
	Condition: Given a requirement to disassemble and store an SUAS, an SUAS, TM 1-1550-695-13&P, TM 1-1550-695-CL, FM 3-04.155, and local SOP.
	Standard: Disassemble and store SUAS IAW TM 1-1550-695-13&P, TM 1-1550-695-CL, FM 3-04.155, and local SOP.
1020	**Title:** Complete Unmanned aircraft Operator Level Maintenance
	Condition: Given a requirement to complete SUAS unmanned aircraft operator level maintenance, an SUAS, TM 1-1550-695-13&P, TM 1-1550-695-CL, FM 3-04.155, and local SOP.
	Standard: Complete SUAS unmanned aircraft operator level maintenance IAW TM 1-1550-695-13&P, TM 1-1550-695-CL, FM 3-04.155, and local SOP.
Master Trainers	
Task	***Description***
1021	**Title:** Prepare Lesson Plan for SUAS Instruction
	Condition: Given a task to be trained, a subject relating to SUAS, target audience, a list of available resources to include training aids/equipment, ADP 7-0 and the United States Army Aviation Warfighting Center Instructor Pilot Handbook.
	Standard: Develop a lesson plan that provides a training objective, content, and training standards for a selected task or SUAS-related subject.
1022	**Title:** Conduct SUAS Academic Instruction
	Condition: Given a subject relating to SUAS to be trained, a lesson plan, target audience, reference material covering the subject, a list of available resources to include training aids/equipment, ADP 7-0 and the United States Army Aviation Warfighting Center Instructor Pilot Handbook.
	Standard: Train an SUAS-related academic subject IAW the lesson plan.
1023	**Title:** Conduct SUAS Flight Instruction
	Condition: Given flight training in an SUAS, target audience, reference material covering the subject, a list of available resources to include training aids/equipment, ADP 7-0 and the United States Army Aviation Warfighting Center Instructor Pilot Handbook.
	Standard: Train SUAS flight subjects or task(s) IAW the lesson plan.
Unit Selected Tasks	
Task	***Description***
2001	**Title:** Complete Mobile Operations
	Condition: Given a requirement to complete Mobile Operations with an SUAS unmanned aircraft, an SUAS, TM 1-1550-695-13&P, TM 1-1550-695-CL, FM 3-04.155, and local SOP.
	Standard: Complete Mobile Operations with an SUAS unmanned aircraft IAW TM 1-1550-695-13&P, TM 1-1550-695-CL, FM 3-04.155, and local SOP.
2002	**Title:** Implement Covert Approaches
